HOW TO USE THE MICROSCOPE.

NEW EDITION—NOW READY.

PRACTICAL HINTS ON THE SELECTION AND USE OF THE MICROSCOPE.

INTENDED FOR BEGINNERS.

By JOHN PHIN,
Editor of "The American Journal of Microscopy."

The great favor with which this book has been received, has encouraged the publishers to prepare an entirely new set of plates for it. The new edition, therefore, is not a mere reprint of the old, but will be enlarged to nearly double the size, and at the same time will be improved by the addition of some thirty or forty illustrations, including four full page engravings, handsomely printed on fine toned paper. Notwithstanding these additions and improvements, the price will remain the same—75 cents post-paid.

RURAL AFFAIRS.

By JOHN J. THOMAS.

SEVEN VOLUMES NOW READY.

Price, Post-paid, \$1.50 Each, Sold Separately or Together.

Being a reprint on larger, finer and heavier paper, of the very valuable articles in every department of Rural Economy, which have heretofore appeared in annual numbers, from 1835 to 1875, inclusive, under the title of the *Annual Register of Rural Affairs*. These volumes contain about 31 pages each, or over *Twenty-Three Hundred Pages* in all, of reading matter, and are illustrated with more than *Three Thousand Engravings*, a large part of them from drawings and designs made expressly for the purpose. A brief Abstract of the Contents of the several Volumes is subjoined, although necessarily so compressed as to convey but a very incomplete idea of the number and variety of the topics embraced, and the concise and practical manner in which they are treated:

VOLUME ONE.

FOUR HUNDRED AND FORTY ILLUSTRATIONS.

Country Dwellings.—Laying Out Grounds.—What Fruits to Choose.—Domestic Animals.—Fruit Culture.—Farm Buildings.—Farm Implements.—Butter and Cheese Making.—Rural Economy.—Fruit Seats and Structures.—School Houses.—Weights and Measures.—Domestic Economy.

VOLUME TWO

FOUR HUNDRED AND FIFTY ILLUSTRATIONS.

A Complete Country Residence.—Country Houses.—Fruits and Fruit Culture.—Flower and Kitchen Garden.—Farm Buildings.—Farm Management.—Farm Fences and Gates.—Domestic Animals.—Nursery Lists.—Ornamental Planting.—Implements of Tillage.—Other New Implements.—Rural and Domestic Economy

VOLUME THREE.

FOUR HUNDRED AND FORTY ILLUSTRATIONS.

Workmen's Cottages.—Grounds and Greenhouses.—Farm Buildings.—Architecture.—Farm Husbandry.—Weeds and Grasses.—Practical Entomology.—Fruits and Fruit Culture.—Flowers.—Vegetable Physiology.—Domestic Animals.—The Dairy.—The Poultry Yard.

VOLUME FOUR.

THREE HUNDRED AND EIGHTY ILLUSTRATIONS.

Farm Work.—Orchard and Nursery.—Kitchen and Flower Garden.—Greenhouse.—Road Making.—Cheese Dairy.—Entomology.—Country Homes.—Pruning.—Poultry.—Fruits and Flowers.—Domestic Economy.—Domestic Animals.—Implements and Inventions.—Woodlands.

VOLUME FIVE.

FOUR HUNDRED ILLUSTRATIONS.

Grape Culture.—Milk Farming.—The Duck.—Turnips and their Culture.—Garden Insects.—Reapers and Mowers.—Rotation of Crops.—Small Fruits.—Shrubs.—Labor Saving Contrivances.—Vermin.—Wheat.—Hedges.—Potatoes.—Rural Improvements.—Fruits.—Strawberries.—Flowering Plants.

VOLUME SIX.

FOUR HUNDRED AND FORTY ILLUSTRATIONS.

Culture of Indian Corn.—Draining, Fencing and Wall Making.—Measuring and Mapping Farms.—Town and Country Roads.—Farm Buildings.—Culture of the Carrot.—Destructive Insects.—Plowing without Dead Furrows.—Weed Hooks and Chains in Plowing.—Plowing with Three Horses.—Fruit Culture.—Cheese Making.—Hay Making by Machinery.—Implements and Machines.—Ornamental Planting.—Domestic Economy.—Miscellaneous Papers.—The Farmer's Register.

VOLUME SEVEN.

FOUR HUNDRED AND SEVENTY ILLUSTRATIONS.

Laying Out Home Grounds.—Cooking Food for Animals.—The Great Sale of the Century.—The Circle of Fruits.—Houses of Moderate Cost.—Construction of Greenhouses.—Barns for Different Purposes.—Piggeries and Pig Raising.—Cranberry Culture in New Jersey.—Small Fruit Culture for Profit.—Ornamental Plants.—Pigeons, Management and Varieties.—Tying Knots.—Accidents and Emergencies.—Market Gardening for Profit.—Suggestions in Rural Economy.—Miscellaneous Papers.—The Farmer's Register.

Either of the above books sent post-paid on receipt of price, by

ORANGE JUDD COMPANY,
245 BROADWAY, NEW YORK.

A Book for the Fireside in the long Winter Evenings.

The Farm-Yard Club of Jotham.

An Account of the Families and Farms of that Famous Town.

By GEORGE B. LORING.

NOTICES BY THE PRESS.

The Farm-Yard Club of Jotham, an Account of the Families and Farms of that Famous Town, so happily combines the information which both the amateur and the professional farmer need, with the charms of individual experience and characterization, that it will please a great variety of tastes. The number and excellence of the illustrations deserve special mention, the designs being lastefully conceived and skillfully executed, and having, moreover, a peculiar appropriateness.—*Globe*, Boston, Mass.

Dr. Loring has given us a book which is at once cyclopedic in its information, entertaining for its wit and humor, and interesting as a story, for the bright thread of real life and love that runs through it.—*Golden Rule*.

Octavo, 603 pages, with 70 Illustrations of Characters, Country Scenes, Farm Animals, and Implements, by Champney, Rose, Lathrop, Forbes, and others. Price, post-paid, \$3.50.

The Poultry Yard and Market;

OR,

A Practical Treatise on Gallinoculture.

By Prof. A. Corbett,

Inventor of the New Process for Hatching Eggs and Raising Poultry, by means of Horse Manure alone, for which Gold and Bronze Medals, and several Diplomas, have been awarded by State and County Fairs, and the American Institute.

CONTENTS.

The artificial incubation of the past and present.—Researches and success with the use of horse-manure.—The sort of manure.—How to use it.—The best breed to keep.—Diseased feet in chickens.—Infections water for chickens.—How hens sit only six days.—How to see whether eggs are fertilized.—How twenty dollars profit can be obtained from each hen.—Advice to the ladies about raising poultry.—How to establish a poultry-yard.—Practical rules for making money.—How to help chickens out of the shell.—Cooked food for poultry.—How to keep the chickens growing.—Treatment of hens that eat eggs.—The number of hens to a rooster.—How to keep eggs for winter.—How to fatten and dress poultry for market.—Diseases and their cure.

PRICE, POST-PAID, 50 CENTS.

Either of the above books sent post-paid on receipt of price by

ORANGE JUDD COMPANY,
245 BROADWAY, NEW YORK.

A Trochar for Cattle-Men.

In June of 1872 we gave illustrations of a Trochar and Camula to be used in ringing a bull, and on page 13 (January) and page 97 (March) of the *American Agriculturist* for 1873 (copies of which may be got from this office for 15 cents each) we described the use of this apparatus in relieving hoven in cattle. These articles have brought out a large demand for Trochars, and failing to find just the right kind among the makers of surgical implements, we have induced an establishment to undertake their manufacture. We give herewith a small engraving of the Trochar. These articles are now in the trade, and may be had of most dealers in agricultural implements. Those who can not get them from dealers can receive them from this office, prepaid, for \$1.00.

ORANGE JUDD COMPANY, 245 Broadway, N. Y.

A COPPER BULL-RING,

2½ inches in diameter, of the most approved pattern, with screw-driver for putting it together, will be sent, prepaid, on receipt of \$1.00. Address

AMERICAN AGRICULTURIST

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD COMPANY,
PUBLISHERS AND PROPRIETORS.
Office, 245 BROADWAY.

ESTABLISHED IN 1842.

TERMS: \$1.50 PER ANNUM IN ADVANCE;
4 Copies for \$5; 10 for \$12; 20 or more, \$1 each;
10 Cents additional must be sent with each Sub-
scription for postage.—Single Number, 15 Cents.

Entered according to Act of Congress, in December, 1877, by the ORANGE JUDD COMPANY, at the Office of the Librarian of Congress, at Washington.

VOLUME XXXVII.—No. 1.

NEW YORK, JANUARY, 1878.

NEW SERIES—No. 372.

THE MUSMON OR WILD SHEEP OF EUROPE—(*Ovis Musimon*).—Drawn and Engraved for the American Agriculturist.

The origin of our domesticated sheep will probably ever remain a mystery. From which of the known races of wild sheep it has been derived, is a matter of dispute, or at least of difference, amongst naturalists. Indeed, it is and has been a question which of these wild races is really the aboriginal one, or whether there was but one or more than one. Whoever has carefully studied the subject, and is without prejudice, or does not seek to support a foregone conclusion, would probably consider the different wild sheep to have been derived from one aboriginal race, and the different domesticated varieties that have a very ancient history, to have sprung from the more ancient wild races. Thus we might consider with reason, that the Argali or Asiatic Mountain Sheep, was the progenitor of our Rocky Mountain Sheep, and of the domesticated Asiatic races, as well as of the European wild mountain sheep the Musmon, the subject of the

above illustration; and this last in turn may reasonably be supposed to have been the ancestor of the very different Spanish Merino, and consequently of our own American Merino. The gradual evolution of an improved breed from a very coarse ancestry, and the wonderful refinement that is possible in course of even a few years of careful breeding, go to explain very satisfactorily many otherwise startling differences in the structure, habits, and other general characteristics of an animal. It is, therefore, far from difficult to account for the widely different characters of our Merino and this ancient wild race, which is, doubtless, at this time nearly, if not precisely, like what it was two or three thousand years ago. The Musmon inhabits the mountains of Southern Europe, and of the Islands of Crete, Cyprus, Sardinia, and Corsica. It formerly abounded in Spain, and is supposed still to exist in the mountains of some of the wilder por-

tions of that country. The male has horns two feet in length, but the female is often hornless. These animals gather in flocks of some hundreds, except at the breeding season, when the large flocks separate into small ones, consisting of one male and a few females. They have been known to breed from the domestic sheep, and the progeny is fertile. Such cross breeding was common in the time of Pliny, or over 2,000 years ago, and the produce was mentioned by this writer as being termed Umbri. The coat of this sheep is outwardly a brownish hair, covering an undercoat of fine, gray wool, which is short, but full of spirals, and very closely serrated upon the edges. It is interesting to consider if the Spanish Merino inherits its "fine, short wool, full of spirals, and closely serrated," from this original race, which inhabited the country where the former first became known to the Romans, who carefully bred and greatly improved it.

Taking Out Stumps.—"W. A." Lee-morn, Mo. It will certainly pay to take the stumps out of a field, so that a mower can be used. The gain in time and labor made would make it worth while to spend a dollar for each stump, unless they are very closely set. With giant powder, or even common powder, a stump may be blown out for less than this sum.

Galvanic Chains, Belts, and other electrical appliances. We have numerous letters concerning various contrivances for applying electricity as a remedy, and we can only give a general answer. These things are not sent to us for examination, and we have no special knowledge of the different kinds now offered. Electricity in some of its forms has been found to be a useful remedial agent. Whether it is likely to be useful in any particular case, we can not say. We do not practise medicine, and if we did, we should not give advice without seeing the patient. Electricity being an agent about which people in general know but little, is one of the things made use of by quacks. Some of the pretended electrical appliances we have seen, are thoroughly unscientific in construction, and can have no more medicinal effect when applied to the body than a belt or pad of leather, or other inert substance.

AMERICAN AGRICULTURIST.

NEW YORK, JANUARY, 1878.

A new year now begins which promises to be one of eventful interest to the agriculturist and all others engaged in productive industry. For many years the nation has been undergoing a severe process of liquidating debts, casting off fictitious ideas of values and, to use a common expression, "coming down to hard pan." At the outset of this revulsion, which was inevitable after the previous years of an inflated and deceptive prosperity, farmers were the first to suffer, and the most seriously afflicted. Nearly every one was in debt for borrowed money or for property, machinery, implements, or stock. Prices of produce first fell, but the cost of all things needed for the farm and household, together with the price of labor, kept up, and farmers had more than their share of adversity. Along with the business troubles, came unfavorable seasons, fatal disease among stock, and the "hateful grasshopper," with other pests. But out of adversity grew an improved condition which now appears to have placed the farmer beyond the reach of trouble, and to promise him in the future a lengthened season of prosperity, should no untoward accident occur. After the disagreeable experiences of the past years we now have good reason for congratulation. We are emboldened to act once more with the usual native enterprise of the American people. Circumstances of all kinds favor this. The bottom has been reached. For the past 20 years the prices of many things which the farmer purchases have not been lower than now. Labor is lower than ever before. Hundreds of thousands of laborers are waiting for work, yet there is work for every one. What a change for the better would it be if all this labor could be turned at once to productive account! Considering the vast amount of work that is waiting to be done, the necessary improvements of roads, fields, buildings, tools, implements, and other things upon which the prosperity of agriculture depend; the vast field in fact which is opened up by the absolute need for the best and highest culture of our soil, and the most profitable exercise of the farmer's art, one is amazed as he ponders over the results that might and would be attained were all this labor employed and all these improvements set in

operation and made. What fruitful fields, where now are barren wastes or worthless weeds; what wealth, where now is poverty; what populous villages, where now are wretched hamlets; what comfort and enjoyment where now misery and destitution prevail. Here is the labor and there is the work to be done; what keeps these apart, and hinders the desirable result? Certainly every farmer in the land can do something at this time to change all this, and hasten the looked for prosperity.

Hints for Work.

Planting and Sowing may be done in many of the Southern States. Where the season admits of it, potatoes may be planted this month, and will ripen in June. It is only necessary to cover the sets deeper than in summer planting, and if a frost is probable, draw earth over the young plants with the hoe. Oats sown this month will do as well in most cases as those sown in the fall.

The Hessian Fly is active in the South at this season, while dormant in the colder North. Anything that will disturb the larva in its operations will be beneficial; as will also any fertilizing application that will strengthen the plants. Rolling the wheat, sowing 5 bushels of salt, or 50 bushels of unleached wood ashes, or 10 bushels of soot per acre, have all been found of use in destroying the insects and in stimulating the growth of the wheat.

Breaking Up the Land, for the main crops of cotton and corn, should be begun this month. Secure laborers for the year. The planter can now select the best help, while later he must take just what he can get. The best laborers don't wait long to be hired, and those who look out first are best served.

Fences are to be Repaired or made, and much draining may be done, both in the North and South.

Hired Labor is Cheap; for a few dollars, and by exercising judgment, one can now get more work done than he could for many years past. The laborer who stands idle when he may earn 50 cents, is unwise; a little is better than nothing.

What May be Done?—Stone may be got out and hauled into heaps where it may be wanted for sale or for use. A well may be dug in the barn yard. Posts and rails may be got out in the rough, hauled to a convenient spot, and piled up to dry. Slabs from a saw-mill make excellent fence posts, and can usually be purchased very cheaply, and these may be drawn home. Springs may be cleaned out and walled up. Rocks may be undermined and toppled into large holes and buried. To a willing worker, there never comes a time when there is nothing to be done; and much may be done now to prepare for the busier period which will soon be at hand.

Wintering Horses.—Working horses, 25 years old, are very rare, and yet at this age a horse may be vigorous and useful. The duration of a horse's life is 30 years, if he is well cared for, and in his old age moderate work may be expected from him. A large proportion of horses are ruined before they are 5 years old by over work, improper feeding, neglect, and abuse. Neglect and improper feeding find more victims than over-work, for if a horse in his prime is properly fed and cared for, he can scarcely be hurt by steady work.

Feed Should be Given regularly as to time and quantity. A horse has a comparatively small stomach. Five pounds of cut hay, and three quarts of ground feed, should make a full feed for a large horse. Horses that are worked on the road at more than a walking gait, should have the hay reduced to 3 pounds and have 4 quarts of the feed. If the feed is moistened with water, give no drink until an hour after feeding, and none immediately before.

Good Grooming is necessary to good digestion and health. The functions of the skin are very important. The skin is an excretory organ as well as one which affords covering and protection to the muscular tissues. Cleanliness of the skin is as necessary for the health of a horse as for that of a man. The skin exfoliates or throws off in scales the used up portion, and this dusty matter should

be brushed out of the coat. The irritation by the brushing stimulates the skin, and assists this healthful action; but the irritation should not be too severe. A moderately hard brush is preferable to a hard, sharp curry-comb.

Provide a Card for the Cows, and use it at least twice a week; remove all adhering filth every morning, and keep the feet clean; else sores will very probably occur between the hoofs.

Incoming Cows, more especially those that are high-bred and have been well fed, should be judiciously starved for two or three weeks previous to calving, and for a week after it. Feed such cows only dry hay, or partly hay and partly cut straw, with a little bran and a handful of salt. The milking of an incoming cow just previous to her calving, should be avoided, as tending to unduly stimulate the organs and produce the very trouble that is sought to be prevented.

Calves and Yearlings, and cows and oxen as well, when infested with lice, should be freed at once by rubbing the skin with a mixture of sweet oil and kerosene in equal parts. During the winter young animals should be kept growing by means of nutritious food, good shelter, and cleanliness.

Separate Stock into different grades; or feed these at different times if separate yards are not provided. Strife and worry at feeding times should be prevented by these or some other means.

Sheep require a plenty of fresh air. Their warm coat protects them from the cold, and if they have a dry yard, they are better out of doors in fine weather than in a close shed.

Water should be provided in abundance for all the stock, and that drawn from a well is preferable to any other. It is not only purer, but—what is of importance—it is comparatively warm and does not chill the animals. No animal should be compelled to eat snow for drink if it is expected to thrive.

A Pump that will not Freeze, should be placed in every barn-yard. Blunt's non-freezing, out-door, iron, universal pump, surpasses any other we know of for this use or for the house yard. It may be placed over a cistern or a well; however deep it may be, it cannot freeze, and it has an effective device for aerating the well. It can be used as a force pump, and by means of a hose, water may be carried into any of the stables, yards, or pens.

Swine intended for pork should by this time have been fattened and disposed of. Store pigs, if well-fed and housed, will make good growth all through the winter. Nothing helps them to thrive more than slightly warm feed given often. Growing animals should not be gorged with food. A light meal, given four times a day, is better than two heavier ones. It is very easy to over-feed young pigs, and cause indigestion and stoppage of growth.

Grade Pigs are preferable to any pure bred ones for the farmer. As a rule, it will be found a mistake for a farmer to keep pure bred animals except males to produce grades. High-bred animals are nearly always smaller and more finely organized than their grade progeny. Their greatest value consists in producing an improved progeny from our common stock. This is large in size, and in every way more valuable for the market or for home use than the pure bred sire would have been. In no kind of stock is this fact more manifest than with swine. No matter what kind of breed of pigs is kept, this rule will hold good.

Brood Sows, coupled this month, will have pigs in May, which is an excellent season for the pigs. The weather being then warm, and the clover in fine condition for pasturing, the young pigs will make a rapid growth, and will soon surpass those farrowed two or three months earlier, unless cared for in a better manner than is usual. By all means, procure a pure bred boar.

Poultry.—The egg-basket can only be filled now, by giving warm feed and providing a warm, dry house. Clean out the roosting places every week.

Disinfectants.—Deodorizers are not always disinfectants, but nevertheless as many of these substances absorb or neutralize what would—if neglected—soon become infectious matter, they may be

practically classed as disinfectants, and should be used as such. Those most easily procured, and the most useful, are ground gypsum, sulphate of iron, (copperas), and sulphuric acid, largely diluted. Any one of these *should* be used in every manure cellar, and is to be recommended for stables, pigpens, cow-sheds, and poultry-houses. The gypsum may be scattered freely about the floors, or thrown upon the manure; the copperas should be dissolved in water, at the rate of 10 pounds to the barrel of the latter; the sulphuric acid mixed with water in the same proportion, and the liquid scattered over the floors or upon the manure.

Leisure Time should be usefully employed. The winter is the time for study and reading. This is work of the most useful and profitable kind. Many of the most intelligent farmers set apart a certain portion of their yearly income for the purchase of books and papers, and certainly no money can be put to a better purpose. In choosing these, the necessities of the mother and daughters should not be neglected, but should be provided for. The success of the farm largely, and the comfort of the household almost entirely, depend upon women's work, and the women should be provided with means for doing their work most effectively.

Notes on Orchard and Garden Work.

In whatever occupation one may be engaged, he is more ready at the beginning of a year, than at any other time, to look forward and lay plans for the future, and also to receive the suggestions of others. It is a good place here, at the beginning of the year, to answer numerous letters that have been written, and to anticipate others that no doubt are in contemplation, in reference to horticulture as a business. The horticultural novels of a few years ago, of which "10 Acres Enough" was the forerunner and the type, have done a world of harm, by conveying the idea that one, brought up to a city life, or to some mechanical trade, can, with great ease, drop into the cultivation of fruits, vegetables, or flowers, and at once reap large profits in the easiest and pleasantest manner possible. Such teachings are wrong, because they are false. If there is any money to be made out of *cultivating the earth*, whether the crop be wheat or strawberries, Indian corn or cauliflowers, without *work*, hard work, and a plenty of it, we have never happened to learn what the crop is, or where it can be raised. That orcharding small fruit culture, market-gardening, or raising cut-flowers may be made, in many localities, a profitable business, we are fully persuaded, but each one of these requires not only physical labor, and much of it hard work, but one must bring to it, if he would succeed, just that mental activity, and that care and forethought which are needed for success in any other business. If there is any "royal road to riches," it does not lie through an orchard, a garden, or a greenhouse. We would say nothing to deter any one from undertaking any branch of horticulture as a business, but we would dispel the notion that those who have not sufficient energy, skill, application, and tact, to carry on other kinds of business, are any more likely to succeed in these.

"Manuring with Brains" has passed into a proverb, and, like most proverbs, conveys an important truth. The present is the season in which, of all others, the cultivator can best apply "brain manure." Those of us who have kept the run of horticultural and agricultural journalism, and literature, for the past quarter of a century, have seen a marked change in one respect. We rarely hear sneers now at "book-gardeners" and "book-farmers." Experience of real value is not thought to be worth any the less, if recorded in the type of a journal, and if the same matter is presented in the form of a book, if likely to be useful, it meets with ready purchasers, even from those formerly opposed to "book-farming."

As editors, it becomes a part of our duty, if not to thoroughly read, at least to know something of the works published both at home and abroad, and leaving out of question some miserable pieces of job work, where matter is thrown together for the sake

of "making" a book—we have rarely seen a book written by any one who felt that he had something to say, on any branch of horticulture, that did not contain some idea that was worth, to those concerned in the specialty, all the cost of the book. We look upon books, to those engaged in orcharding, in fruit growing of any kind, in vegetable or flower culture, as quite as essential implements, as much tools to be of use in their occupation, as spades, rakes, or other garden tools.

The special works will be mentioned in their proper places, but every cultivator, whether he has to do with acres in field crops, or pints of earth in flower-pots, is engaged with essentially the same materials; the plant, the soil, the air, and water. *Every one* should have an intelligent idea of the mutual relations of these. He should know what a plant is, how it grows, what helps its growth; what is in the soil, and what these constituents, the air and the water, have to do with the plant. We can not do a better service to every intelligent gardener, orchardist, or other cultivator, who would understand the first principles, which underlie all the rest, than to commend to him, whether young or old, a careful study of "How Crops Grow," and "How Crops Feed," by Prof. S. W. Johnson. Not only for study—and whoever masters these works the coming winter will have made a great step towards a "liberal education" in his calling—but as works of reference, they will be found invaluable.

But to the cultivator, in whatever branch, there is another kind of literature to which we would commend him. Works easily to be procured, and, as a rule, worthy of careful consideration—the Catalogues of those dealers in articles belonging to each line of culture, and of those who furnish needed accessories. Do you propose to water your garden? Study the catalogues of the Steam and Hand Pump-makers, or those who furnish Water Rams. Does the stock of tools need replenishing? One can not afford to ignore the improvements of even a single year, and the drills, cultivators, harrows, and improved implements generally, may be a useful—as it will surely be an interesting study. So with fertilizers, the literature of which should be carefully considered. If one is to plant trees, vines, or other fruit-bearing plants; if he is to sow seeds, if he is to be in the fashion with flowers as a business, or if he is to plant, sow, or cultivate anything, whether for profit or for amusement, on a large or a small scale, he will find the catalogues, each in its way, of the greatest help.

"Line upon line, and precept upon precept," is as necessary in horticulture as in higher teachings, and though these Notes are always written afresh, without reference to what has been said in former years, we should be neglectful of our duty did we not repeat some things which have already been said, more than once, and which will be said again and again, by whoever may speak through these columns to his fellow workers.

Each year's experience shows that the only trustworthy label, is *none at all*. That is, every tree, vine, or permanent plant, should be so recorded by its position, that though labels may be lost, though the memory may fail, and what is quite as important in this changing world, though our place may come into the hands of another, the names of each tree or plant should be so recorded that one can readily refer to it himself, and that another will have no difficulty in finding the name. It is a very simple matter; and for safety, there should be a permanent record, from which an abstract may be transferred to a small book, to be carried in the pocket. Ours runs something thus:—"Road from barn east to avenue." "First row south, beginning east end of row;" 2, Beurre 'd Anjou; 4, Duehesse d'Anjouleme; 1, Belle Lucrative, and so on. Then second row south, is recorded in a similar manner. By the use of a few permanent landmarks, all the trees are readily recorded. Strawberries with us, run in strips across the garden, and to prevent running together, are 10, 20, or more feet apart, wherever there is a convenient place. A record of the rows, counting from the barn road, tells the story. The vineyard is a square block, but it is recorded in the same manner, by points of the compass. This matter of record is one of so much im-

portance, as well as convenience, that we are warranted in enforcing it upon every cultivator.

Another repetition, is the importance of ordering early, whatever is to be bought and will be needed, as soon as the season opens, whether trees, plants, seeds, or implements. It is better to order trees in March than in May, but a great deal better to order in January than in March. We have almost no spring. It is generally a jump from winter to summer. In every well-regulated nursery, seed-store, or implement factory, orders are entered by the date on which they are received, and filled accordingly. If trees are ordered now, they will be among the first taken up and sent; they will not start to grow in the nursery rows, or heat if long in transit, and there are similar advantages to be gained in ordering early from dealers in other articles.

In these suggestions at the beginning of the year, we have in mind the fact that whoever starts well ahead of the season will be likely to keep ahead of it. The market gardeners, when they would speak of one who is slack, and always just a little behind his work, say "he lets his pussley get ahead of him." This has a wider application than in the market garden, and in leaving these General Notes to give some brief special ones in the different departments, we wish our friends, in every branch of horticulture, a successful year—and may none of them find that their "pussley" is getting the better of them.

Orchard and Nursery.

"*Brain Manure*,"—The orchardist, quite as much as any other tiller of the soil, needs that fundamental knowledge to which we have referred above, and which we have stated is no where so well furnished in any language as in Prof. Johnson's "How Crops Grow," and "How Crops Feed." He also needs works which shall instruct him in the manipulations of his occupation, and we do not know of any one work which is so full of just the information he needs, to aid him starting anew, or to keep at hand for daily reference, as

"*The Fruit Garden*," by Patrick Barry.—We have often thought that the title was unfortunate, as it hardly gives an idea of the scope of the work. In the present subdivision of horticultural pursuits, we apply the name "Fruit Garden," to a ground more especially devoted to small fruits, while this is by far the most comprehensive work on

Fruit Culture in General, that we know of. There are some French works that compare favorably with it in some respects, but we know of no English work that is at all its equal. It begins at the beginning, and teaches in the plainest language, and with abundant illustrations, every step from raising the stock, budding or grafting it, planting it in the orchard, caring for and pruning it, to gathering the fruit, and besides this it gives a list, with brief descriptions, of the most generally useful varieties of each fruit. While of equal value throughout, that which distinguishes this work from all others, is its minute directions for the details of

Nursery Practice.—It is no disparagement to other establishments, to say that the nursery of Ellwanger & Barry is the largest in the country, and one of the oldest. In his "Fruit Garden," while Mr. Barry gives the management and principles which have been found successful in practice on the large scale, required in a commercial establishment, he does not forget the wants of the amateur. One of the best features of the work is the freedom with which, what some smaller men regard as "trade secrets," are told, and one feels that nothing is withheld, for fear some one else may know as much as the author. Next in general utility we place

"*The American Fruit Culturist*," by John J. Thomas, to which much of what we have said about Mr. Barry's work will apply. Though it is not so full in nursery details, its larger descriptive list of fruits may make it desirable to those who do not care so much for growing the trees, as they do for them after they come from the nursery, and their future management and culture. The work by Doct. John A. Warder, entitled

"*American Pomology*," which has not, unfortunately, gone beyond apples; it is rather unfortunate

also in its title, as the volume is largely devoted to the nursery details for which we commended Mr. Barry's work. It is the only work that we know of which gives the rapid, labor-saving management of the Western nurseries, and its chapters on general operations are the results of the observations of one whose opportunities have been abundant, and of a long and successful experience. The peculiarly Western varieties of apples, are described in full, as are all others in general cultivation.

Downing's "*Fruits and Fruit Trees of America*,"—Many will wonder why this was not placed first upon the list. As a treatise on pomology, a record and descriptive account of all the fruits in cultivation, it is invaluable, but other works are better suited to the general farmer, and the orchardist whose operations are limited.... Those who devote themselves to the cultivation of some particular fruit, should have the works devoted to it. Warder's has been noticed as a special treatise on apples.

Peach Culture has methods and requirements unlike those of ordinary orchards, and these are given in Fulton's "*Peach Culturist*," in which the management of the great peach orchards in Delaware and Maryland is given in full detail.

"*Pear Culture for Profit*" is the title of another valuable special work, by P. T. Quinn, who, having cultivated pears largely, and made them profitable, tells how he did it, and the kinds he grows.

Orchards Old and Young, in the Northern States, need such care as is mentioned in last month's Notes.... Protect trees, especially young ones, from intruders of all kinds.... Trample the snow around young trees to prevent mice from working at them.... Smear the trunks, especially of young trees, with blood, or rub them with bloody flesh, to keep off rabbits.... Cut away clusters of eggs of the Tent Caterpillar, whenever seen near the ends of the twigs. These are the chief points, and it is necessary to observe them all through the winter.... Cions may be cut, labeled, and stored in damp saw-dust, or sand.... Cart manure to the orchard.

In the Southern States manure and shallow plowing the orchard may be done. In many localities this is the most favorable month for planting, pruning, and other spring work.

Those who have the volume for last year (1877) will find in the Notes for January suggestions about varieties that will be of aid to the inexperienced.

Fruit Garden.

It may be necessary to say to our new readers that under this head we place what are known as "small fruits," including grapes, and the dwarf forms of the larger fruits, such as the amateur grows in the garden rather than in the orchard. For the cultivator of these, there is a number of special works, while most of the

General Works, mentioned under "Orchard," include the small fruits also. The "Fruit Garden," by Barry; "American Fruit Culturist," by Thomas, and Downing's "*Fruits and Fruit Trees*," all treat of small fruits in a satisfactory manner. Of general treatises on fruits of this class:

"*The Small Fruit Culturist*," by A. S. Fuller, is the chief and most complete. Its excellence is attested by its large sale, and its translation into his own language, by one of the most eminent of German pomologists—Dr. Lueas.

"*Manual of the Culture of Small Fruits*," by E. P. Roe, is a brief compendium, giving the author's experience and methods, and is eminently sensible and useful. In the way of special treatises,

Works on the Grape Vine are the most numerous. "The Grape Culturist," by A. S. Fuller; "Mohr on the Grape Vine," Chorlton's "Grape Growers Guide," and "My Vineyard at Lakeview," are the leading works.

Strawberry Culture is included in Fuller's "Small Fruit Culturist," and he has besides a special work, "The Illustrated Strawberry Culturist." "Strawberry Culture," by Morrick, is another special and useful work, giving New England methods.

Cranberries belong among the small fruits, but their culture can only be profitable in certain locali-

ties, and is so peculiar as to require a special work. "The Cranberry Culturist," by J. J. White, gives every needed detail, and is a model of excellence and completeness in the way of a monograph.

Dwarf Fruits.—Apples, pears, and other fruits, which usually grow upon large trees, may be dwarfed, and trained in the pyramid or bush form, only a few feet high. They give, for their size, large crops of the finest fruit, and the amateur, whose grounds are small, will find their culture full of interest. The works on general fruit culture, already mentioned, especially Barry's "Fruit Garden" treats of these, while "The Miniature Fruit Garden," by Thomas Rivers (England) is especially devoted to dwarf trees.

Work in the Fruit Garden was sufficiently indicated last month. If the strawberries have not been covered, do it at once. Draw manure to where it will be wanted. Take advantage of mild spells to finish up pruning of grape vines, currants, etc.

In the Southern States soil may be prepared and planting may be done in many localities.

Kitchen and Market Garden.

In no kind of cultivation is success so dependent upon the abundant manuring of the soil as here, and in no other department does "Manuring with Brains" tell better. The appearance of

"*Gardening for Profit*," by Peter Henderson, was an important event in garden literature. It was the first work that told the story of those who raised vegetables for profit. It told the whole story without any mental reservations, and its success and its usefulness have been unequalled. While written to give the methods followed by market gardeners, it is a work that every private gardener should have.

"*Money in the Garden*," by P. T. Quinn, and "Farm Gardening and Seed Growing," by F. Brill, while they cover similar ground, are in many respects quite unlike "Gardening for Profit," and both valuable to the cultivator.

"*Gardening for the South*," by W. N. White, has its scope indicated in its title, though its usefulness is not limited to the Southern States. A number of garden crops are often cultivated on the large scale, and for those who would grow these, works on

Special Crops are prepared. Among the prominent works of this kind are, "Onions, by 17 Practical Growers;" "Onion Raising," by Jas. J. H. Gregory; also works by Mr. Gregory on Squashes, on Cabbages, and on Carrots, and other roots. There is a special work on "Potato Culture," by Compton. These and other small treatises are of great value to any who propose to undertake the special cultures of which they treat.

"*The Vegetables of America*," by Fearing Burr, is an instructive history of the origin and varieties of the various vegetables, including the rarer kinds, and a valuable work of reference.

Work in the Garden consists in looking after the stored crops, that no injury may come from freezing, or from heating on account of too close covering.... Cold-frames need daily care; give air on all but the very coldest days, and when the temperature is up to 30°, or above, remove the sashes in part or entirely.... Manure heaps must not overheat, nor get so much chilled that fermentation will not go on; turn over the pile when too hot, and give water if at all dry.

In the Southern States hot-beds may be started for early vegetables; early potatoes planted, in light soils, and the seeds sown of such hardy vegetables as beets, turnips, spinach, peas, and lettuce—provided the soil is in proper condition.

Flower Garden and Lawn.

Those who propose to improve their places, without calling in the aid of a landscape gardener, will find the elaborate work of Mr. Weidenman,

"*Beautifying Country Homes*," a most useful guide, as it furnishes a great variety of plans, and gives practical suggestions of great value.... Downing's "Landscape Gardening" is a standard work on the principles of the art, and others are given in the Publisher's book list. As a general guide for the

Management of Small Places, such as grounds in cities and villages, "Gardening for Pleasure," by Peter Henderson, will meet the wants of many, as it includes in one volume directions, not only for laying out the ornamental grounds, but for the management of the fruit, vegetable, and flower gardens. The best work on what may be called

Old-Fashioned Gardening, is Breck's "New Book of Flowers," in which the author talks about the usual hardy and tender flowers and shrubs in the pleasing and familiar manner of one who loves them.

Ornamental Flower Beds, and the planting of flowers and foliage in masses, are treated in "Practical Floriculture," and "Gardening for Pleasure," both by Peter Henderson.

Tree Planters will find in "The Book of Evergreens," the best work on evergreens in the language. It also treats of evergreen hedges.

Special Treatises, such as "Parsons on the Rose," and others, will be found in the book list.

Work in this Department consists in keeping everything in order, and in preventing injury from animals, and those thoughtless people, who disregard paths when snow is on the ground, and drive or walk "across lots." The manner of preventing injury to evergreens by snow, is given on page 22.

Greenhouse and Window Plants.

For the culture of plants under glass, whether in the greenhouse or in the window, the most generally useful works are "Practical Floriculture," and "Gardening for Pleasure," by Peter Henderson, the first named being more especially for those who cultivate flowers for sale, though the wants of small growers are not overlooked, while the other, intended especially for amateurs, gives more space to the window cultivation of flowers.

Window Plants should by this time be in flourishing condition; their health may be promoted by a thorough showering at least once a week; when the weather will allow, they may be set out doors; otherwise in a bath-tub or sink, and showered copiously, to remove dust. The hints as to insects given last month, will be timely so long as the plants remain in the house. Bring pots of bulbs from the cellar from time to time, to have a succession of flowers. Camellias flower best in a cool room, the buds are less likely to drop, and the flowers last much longer; when growth commences, give them a place at a warm window.

Severe Weather.—It happens almost every winter, that there are two or three nights so severely cold that the ordinary heating appliances will not keep the room warm enough to prevent freezing, at least at the window. At such times the plants should be placed in the middle of the room and covered with a sheet, or even with newspapers.

Frozen Plants will often recover if taken to a room where the temperature is just above freezing, and allowed to thaw very gradually. The change to a very warm room would be injurious.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our daily record during the year, show at a glance the transactions for the month ending Dec. 12th, 1877, and for the corresponding month last year:

two-rowed, within the range of 70 @ 78c. per bushel. Some very fancy samples of Canada product have been marketed at extreme figures, as high, in a few instances, as \$1.08 @ \$1.10, prime No. 1 closing, however, at \$1 per bushel, free. Receipts of Grain have fallen off, near the close, through the partial suspension of inland navigation. The arrivals of Flour have been large, notably so of the less desirable qualities of Winter and Spring Wheat Extras, which have been accumulating here and quoted unsettled in price. Speculative control of Wheat and Corn supplies worked against regular trade operations. Cotton has been ruling higher, on a brisk movement, largely on speculation, but closed weaker. Wool has been in fair but not urgent request; and has been quoted generally firm. Hay, Straw, and Seeds, moderately sought after, but variable as to price. Hops have been quite active, in good part for shipment, within the previous range. Tobacco has been quoted steady, on a moderately active call for supplies. Naval Stores and Petroleum were depressed and irregular, but left off more firmly, with a firm demand noted. Groceries have been selling more freely; Sugar and Molasses further receded in price, but the former closed stronger; Coffee higher; Teas unsettled. Ocean freights were quoted lower on free offerings of accommodation, leading to an active business, leaving off more steadily, especially for Breadstuffs, Provisions, and Cotton. Grain rates by steam to Liverpool closed on the 12th of Dec. at 8 1/2 d.; to Glasgow at 8 1/2 d.; to London at 8 1/2 d.; to Bristol at 9 1/2 d.; to Hull at 8 1/2 d.; to the Continent at 9 @ 10 d.; to Liverpool, by rail, 7 1/2 @ 7 3/4 d.; London, by rail, 8 d., per bush. Flour to Liverpool, by steam, 2s. 6d.; London, by rail, 2s. 3d., and by steam 2s. 6d. @ 2s. 9d.; Bristol, by steam, 3s. 3d. per bbl. Provisions by steam to Liverpool, 32s. 6d. @ 40s. per ton; Cotton by rail 5/32 d., and steam at 1/4 @ 1/32 d. Grain, by rail, for Cork and orders, at 6s. @ 6s. 4 1/2 d., and to Continental ports, 6s. 3d. @ 6s. 6d.; Italian ports, 6s. 3d. @ 6s. per quarter.

Bees.

A very poor and depressed market marked the opening of the month. The only sustaining influence was that of the demand for foreign shipment, without which, one can not tell to what extreme of lowness prices would have fallen. A gradual improvement, however, is to be noticed, and the month closes with a more healthful market, showing a better demand with some advance in prices. The excessive receipts alone prevented a greater improvement. Extra good Kentucky and Illinois cattle of 1,600 to 1,700 lbs., sold for 11c. for 57 lbs., and 11 1/2 c. for 58 lbs. to the cwt. Medium to good natives, sold for 9c. @ 9 1/2 c. 3/4 lb., and thin steers and oxen, Texans and Colorados, from 8 1/2 c. @ 9c. 3/4 lb.

Milk Cows.

There has been a very poor demand for cows of more than usually poor quality, and these have been in more than usual supply. As low as \$20 has been

paid for cows the past month. Good cows sell for \$65 @ \$70, and are wanted. **Calves.**—Hog-dressed are now arriving in sufficient numbers to affect the price of grassers and live veals. Grass calves sold at the close at 3½ @ 4¼. ½ lb., alive; the best veals brought 9 @ 9½. ½ lb. These prices were an advance, which was gained through the smaller receipts during the month. **Sheep and Lambs.**—Good sheep were never so low in this market as they now are. Mutton is not a fashionable meat, or is not estimated as well as it might be. With present prices, farmers might add to their flocks with profit. The best sheep that have appeared here in some years, sold for 4½. ½ lb., alive, and fine Canada ewes brought 5 @ 5½. ½ lb. Fair lambs ranged from 4 @ 6½. ½ lb., live weight. **Swine.**—The market has been "see-sawing" back and forth during the month, ending where it began, the excessively heavy receipts bringing the scale down rapidly at the close, with a promise of worse to come. Live hogs have been dull at 4½ @ 4¾. ½ lb., and city dressed at 5½ @ 6c. ½ lb.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

Publishers' Notices, Terms, etc.—The Annual Subscription Rates of the *American Agriculturist*, postage prepaid by the Publishers, are: One Copy, \$1.60 a year; Two Copies, \$3; Three Copies, \$4.20 (\$1.40 each); Four Copies, \$5.20 (\$1.30 each); Five to Nine Copies, \$1.25 each; Ten to Nineteen Copies, \$1.20 each; Twenty Copies and upwards, \$1.10 each; Single Numbers, 15 cents, post-paid.—The above terms are for the United States and Territories, and British America. To the above add 14 cents extra per year for papers delivered by mail in N. Y. City, and for copies sent outside of the United States and British America, except to Africa, Brazil, British Honduras, the East Indies, and Mexico. For the last named five countries the extra charge is 38 cents per year, to cover extra postage; Single Numbers, 17 cents, post-paid. **Remittances**, payable to Order of Orange Judd Company, may be sent in form of Checks or Drafts on N. Y. City Banks or Bankers; or P. O. Money Orders; or in Registered Letters, such letters to have the money enclosed in the presence of the Postmaster, and his receipt taken for it, and the postage and registering to be put on in stamps. Money remitted in any one of the above three methods is safe against loss. **Bound Volumes** from Vol. 16 to 36 inclusive, supplied at \$2 each, or \$2.30 if to be sent by mail. Sets of numbers sent to the office will be bound in our regular style for 75 cents (30 cents extra if to be returned by mail). Missing numbers for such volumes supplied at 12 cents each. **Any Numbers** of the paper issued for 21 years past, sent post paid for 15 cents each. **Clubs** of Subscribers can be increased at any time at the club rates, if new members begin at same date as original club.

The German Agriculturist, with its beautiful new cover, and other improvements, is giving great satisfaction. Will our readers please inform their German friends and neighbors of this German paper, issued now for 20 years. It is every way equal to the English edition, with a Special and extra German Department, Edited by Hon. Fred. Münch. Terms, the same as the English edition, with which it may be joined in making up clubs.

Advertisers will find a valuable medium in the *German Agriculturist*. The rates are very moderate, and the paper circulates largely among readers who are not reached through other channels.

Advertisements in numbers entirely unlooked for, crowded in at the last moment, and entirely upset the Editor's plans for several pages of reading matter, which must go over. But these business notices are from "good men and true," and give a good deal of information our readers are interested in. So read through the advertisements, and when writing to any advertiser tell him *where* you saw his advertisement.

N. B.—Please Observe. Take Notice.—It is a waste of time, talent, stationery, and post stamps, to write us a letter and *not sign it* with full name and address. We have no time to devote to nameless people, and the waste-basket receives their letters. Please don't write to ask about advertising "doctors"—we do not know anything about them. Please do not preface your letters with a long apology, stating that you have "never troubled us before." If the inquiry made is a sensible one, it is not "troubling" us. We wish for such, and are glad when they come. If you have taken the paper for five or ten years, and have never before asked a question, we are sorry both on your account and our own. One more request:—Please don't write with pencil, but better that than pale ink. Recollect we have to look through letters by the hundred, and pale ink, or what is worse still, red ink on pink paper is trying.

A Microscope for All. Important Notice!

The Microscope offered to our readers last month, proves to be quite as valuable as we hoped it would be. It is a capital instrument for all the purposes for which it was recommended, and more. We hear of a few who have as yet failed to appreciate its real merits, but we know that comes from lack of experience in using such instruments. We shall try to aid such to a proper understanding of its use. A beginning is made in this paper, (see page 10.)—Many scientific men, and many others familiar with microscopes, have examined this one, and all speak of it with the *highest praise*. We know that when our readers become accustomed to using it properly, it will be a source of much pleasure, and will be turned to practical utility as well.

It costs a good deal more to supply them, than is charged for them above the subscription rates; but this was anticipated, and a round sum set aside by the Publishers to meet the additional expense—the same sum, or more rather, than has in past years been expended upon Chromos for free presentation. And now we want every reader of this journal to have and enjoy one, though it would be a saving of expense if but few take them. Our only regret is that it is not possible to give them outright.

As many thousands of new subscribers are coming in who did not see the last number of this paper, we republish in part, on page 33, the description, etc., of the Microscope, which please read.

Important about the DELIVERY of the Microscopes.

The average cost of delivering one of these Microscopes, with the strong double-cover box needed, is 15 cents, to any point in the United States and the Canadas. We do not add this to the extra charge above the subscription price, and call it 55 cents, because our subscribers come largely in clubs, and all the Microscopes going to one club, can be sent in a single package, unpaid, to some member of the club, who should be designated, and the cost of carriage will be but a trifle on each.—Thus, if 10 or 20 go in one parcel, and the express charges are 25 to 50 cents on the whole, the cost of carriage will be only 2½ to 5 cents each.—We therefore only require the 15 cents when we send them prepaid. *We can not pay this.* There is not profit enough on subscriptions to pay the extra cost of the Microscope above what is charged for them, much less to pay for the carriage also.

We have now a special arrangement with the ADAMS, the AMERICAN, and the UNITED STATES Express Companies, to deliver the Microscopes singly to any point in the United States or Canadas, where they have offices. This arrangement is only temporary, but we hope it may be continued through the winter. They will give us sufficient notice, if it is not continued, to notify our readers in the following number. Where there is no office of any one of these companies, we provide other means of delivery. The terms are:

One Subscriber for 1874 and one Microscope,	{ Taken at the Office or forwarded unpaid,	{ \$2.00.	{ If sent pre-paid,	{ \$2.15.
Two Subscribers for 1873 and two Microscopes,	{do.....	{ \$1.90 each.	{ do.	{ \$2.05 each.
Three Subscribers for 1873 and three Microscopes,	{do.....	{ \$1.80 each.	{ do.	{ \$1.95 each.
Four Subscribers for 1873 and four Microscopes,	{do.....	{ \$1.70 each.	{ do.	{ \$1.85 each.

For terms to large clubs see page 34. The

Order of Delivering the Microscopes, will be in the order of reception of names. "First come, first served." Over 60 men are working on them with machinery. The call is beyond expectation. They will come as fast as made. Let no one be anxious if his Microscope happens to be delayed a few days. It will come in due time sure.

Wintering Cows on Meal Alone, is a subject of much interest to dairymen. The address of Linus W. Miller, read before the American Dairymen's Association, and other meetings, has created much interest in what is now called the "Miller System" of feeding. As innovators upon established customs are apt to be misrepresented (not always intentionally) by their opponents, it is better for those who would investigate the matter, to read Mr. Miller's own presentation of it. This he gives in a pamphlet of 82 pages, which may be had from this office, post-paid, for author's price, 50c.

"The Omaha, Neb., Pioneer," for December, contains much valuable information for those who contemplate emigrating to the West. It is sent free on application to Mr. O. F. Davis, Omaha.

J. B. Root's "Garden Manual,"—The sudden death of J. B. Root, of Rockford, Ill., was noticed just a year ago. He was in his department a leading man, and his contributions to the *American Agriculturist*, and other journals, were marked by great originality, and were valuable contributions to the literature of vegetable gardening. He was largely engaged in seed growing, and the business is now carried on by Mrs. Root, to whom we wish much success. The present issue of the "Garden Manual"—which includes a catalogue—is made up of articles left by Mr. Root, and selections from those that have appeared elsewhere, and characteristically fresh, practical, and sensible.

An Iron Mattress.—Probably the most comfortable of all beds is one of that hardest of substances—iron. Paradoxical as this may seem, we know it, by experience, to be true. Iron in the form of wire may be so woven, netted, and arranged with springs as to make a bed that readily adapts itself to the form, and recovers its shape at once when the weight of the body is removed. We have tried the article made by the "National Wire Mattress Co.," of New Britain, Conn., and find it to be as nearly perfect as a bed be.

The Pennsylvania Fruit Growers' Society will hold its annual meeting at Williamsport, Pa., commencing January 16th, 1878. It is expected that several prominent horticulturists will attend, and address the meeting, and an interesting session is expected. Josiah Hoopes, Westchester, is President, and E. B. Engle, Marietta, Secretary.

The Hessian Fly.—How far does it extend West and South? is what Prof. Packard, Secretary of the U. S. Entomological Commission, would like to know. In order to aid him in studying the distribution and extent of the ravages of this pest to wheat growers, Prof. P. would like specimens from the Middle or Western States. Send so that they will not be crushed, by mail, to Prof. A. S. Packard, Jr., Salem, Mass.

Senders of Papers.—It often happens that one wishes us to see an article he has published in some paper, or to call our attention to some particular article. The most certain way is to cut out the article, giving the name and date of the paper, and send it with the letter. But if a paper is sent for the purpose, please *mark the article* distinctly, by lines drawn against the heading, and also put upon the wrapper "Editorial." Unless these precautions are observed, the paper, among the hundreds that come daily, may never reach us.

The "American Journal of Microscopy," edited by Prof. John Phin, and published in New York, is especially valuable as a means of communication between those engaged in microscopy, and its articles are of a popular character—and not merely for the small class of experts.

The A B C of Bee Culture, is the title of a new Cyclopædia of Apian matters. Part I. contains 48 pages, with 20 engravings, and in the alphabetical arrangement extends to "Comb Honey." It is published at Medina, Ohio, by the author, A. I. Root, at the moderate price of 25c.

New Jersey is a State sometimes sneered at by those who know nothing about it, for its old foggy ways. It easily took the lead at the Centennial Exhibition, and if any other State has published a report of its part in the Exhibition in any handsomer or more complete form than New Jersey, we should like to see it.

To Be Had Without Money.

PLEASE REMEMBER that Our General Premium List, published in October, is still in FULL FORCE, and will be during the winter. Multitudes of our readers, all over the country, can each secure one or more useful and very desirable articles free, by the little trouble required to collect three, four, five, or more, names of those who would subscribe for the Journal if shown to them by some one. Over 20,000 of our readers have received these premium articles, and thousands more ought to get them this month, and during the winter. Every person induced to take and read such a Journal, will be benefitted in the end. The Publishers can not go to individuals to present the paper to them, and they offer these good premium articles as rewards to those who do so. See the list of articles on page 33, and if you have not the Illustrated Sheets describing each article, send immediately for a free copy.

Many persons canvas as a business, receive the premium articles, and dispose of them for cash, (for they are all good and readily salable), and thus realize a fine income. **This Month** is a good time to enter upon such a work.

Take Notice.—The offer of the Microscope to every subscriber, whether in a premium list or not, does not at all interfere with making of lists for premiums, but will rather aid in the work, for every subscriber for 1878 is entitled to call for one of the Microscopes on paying a small extra charge above the subscription price, as stated on pages 33, 34. The Paper alone is worth all that is asked for it. The Microscope is worth to any person much more than the whole cost of both the Microscope and the paper for the whole year.—So push along the gathering names, to secure premiums for yourself, and let all who have it not send a postal card at once for our Illustrated Premium Sheet, which we mail free to all applicants.

The North Western Dairy Exhibition.—The exhibition of dairy products by the North Western Dairyman's Association, was held at Chicago, December 18th, and following days. The exhibition opened with over 2,000 parcels of cheese and butter, from all the dairy States and Canada, and more arrived afterward. President Hewes opened the proceedings with an address, and others followed. The attendance of visitors was large, and the exhibition very successful.

What Scientific Men Say.—Numerous letters and verbal commendations have come from the best practical judges of the real value of a microscope. Among others, **Prof. Phin**, Editor of the *American Journal of Microscopy*, writes, Dec. 11, as follows:

MESSRS. ORANGE JUDD COMPANY:

"I have carefully examined your AMERICAN AGRICULTURIST Microscope, and am delighted with it. Having procured all the lower-priced microscopes offered for sale in this country during the past twenty years, I could not recommend one in my book on the Microscope. This of yours is really good, and shows well all the most interesting common objects. I have just seen clearly, with it, the beautiful globe-animalcule, (so-called), the cellular structure of plants, the trichina or so-called "pork-worms," and several other objects that require good microscopes.

JOHN PHIN."

One of the Most Striking Steel Engravings we have lately seen, is that of **BISHOP JAMES**, in the January Number of the "National Repository." Every lineament of the face is so accurately drawn and printed that the picture is instinct with life. The "Repository," by the way, is a most excellent family magazine, filled with safe reading of a high order. Our old friend, Dr. Curry, who has had long editorial experience, is working well into his new sphere of labor. Not having space for further notice of the "Repository," we refer to the Publishers' announcement on page 32.

The Western New York Horticultural Society, is one of the most useful of the various horticultural associations, and though it, usually, holds but one meeting a year, that one abounds in good results, and we always receive the account of its proceedings—furnished with commendable promptness, with the feeling that we shall surely find something worth reading. While the N. Y. Horticultural Society, holding its meetings and exhibitions in New York City, has florists' plants and flowers as its leading feature, the Western Society gives greater prominence to fruit,

and thus the two admirably supplement one another. The 23d Annual Meeting of the Western N. Y. Society will be held at Rochester, N. Y., commencing on Wednesday, the 23d inst., and probably continue for two or three days. All interested in horticulture will be welcomed, and they are invited to exhibit their products. P. Barry is President, and P. O. Reynolds Secretary and Treasurer—both of Rochester.

Sale of an Arab Colt.—We are informed by Mr. J. J. Parker, of Westchester, Pa., that his Arab colt, "Arab Boy," the portrait of which was published in the *American Agriculturist* for June, 1877, has been sold for \$1,000, to W. C. Myer, of Ashland, Oregon, whose attention was called to the colt by the above mentioned portrait. Mr. P. has long been a very successful importer and breeder of Percheron and Arabian horses.

A Watch-Case Time Table is sent us by the "Dexter Spring Co.," of Hulton, near Pittsburgh, Pa. There does not seem to be any direct relation between the well known carriage spring, called the "Dexter," and a R. R. time table, and we suppose that the "Co." send out these for amusement. It is a little engraved form, to be cut to fit the inside of a watch-case, and ruled so that one can readily write in the time that the cars leave and arrive at any desired point. It is for a hunting-case watch, and when the case is opened, the time and the R. R. schedule are both in sight.

Sundry Humbugs.

To the long-time readers of the *American Agriculturist*, it is not necessary to speak of the aims of this column, but as many new friends always join our circle with the new year, (and this year the number promises to be gratifyingly large), these may need a word on the subject. In the early days of the *American Agriculturist*, an occasional exposure was given of the mock auction and other traps, set by sharpers to catch visitors from the country, and strangers were advised of the tricks practised against them, long before the authorities took up the matter, and broke up this form of swindling. From this small beginning, the exposure of other frauds followed, and the "Humbug Column" soon became a regular and necessary feature of the paper. We say "necessary," because a large share of the fraudulent schemes are directed towards the agricultural community. It is no disparagement to farmers to say this. These sharpers know that men who are so generally honest and upright in their dealings as are farmers, are of all men the least likely to suspect others. This is why such a large share of the swindles are directed towards the rural population; the rogues well understand human nature, and know that men who are honest themselves are slow to suspect others of dishonesty.

THE OBJECT OF THESE EXPOSURES

then, is to warn our readers against fraudulent schemes of all kinds, and especially those directed against the agricultural community. While we fearlessly make such exposures as are demanded by the public welfare, it is to be distinctly understood that these columns can not be used to redress any private grievance, and it will do no good to write, as some do, a request that we show up this or that person as a "humbug," simply because the writer feels that he has been wronged by the party complained of. It is only those who are defrauding the public at large, and whose operations are detrimental to the general welfare, that are entitled to a place here. It has been said that no human ingenuity has been able to construct a lock so perfect that one with a little more ingenuity can not pick and open it. It is the same with laws as with locks, and it does not seem possible for the law-makers to frame a law so well guarded that an acute person can not get around and avoid it. An illustration of this is seen in the case of the parties who have been operating under the name of

RUSSELL & CO.

Circulars, pretending to be at first a settling up of the affairs of the "Louisville Lottery Association" by a supplementary drawing, and later enlarged to include "the Various Legal Lotteries," have been sent far and wide. To judge from the bushels that have come to us, the mails must have been loaded with them. These at first

offered "a Gold Watch and Chain valued at \$150"—to be had by payment of an "assessment" of \$15—and later a lot of "Gold Jewelry" of 80 (more or less) different patterns, "valued at \$280" (more or less), to be had by paying an "assessment" of \$14 (more or less). This has been going on for months, and while we felt that it was the biggest kind of a swindle we could not prove it. All we could do was to warn our readers, on general principles, that people did not, could not, and would not sell for \$15—watches, or anything else, worth more than that sum. Why people, when they receive such an offer, do not at once

TAKE A COMMON SENSE VIEW

of the case, is beyond our comprehension. But they don't. They send these circulars to us by the dozen and hundreds, asking our "opinion." What opinion can we give other than this? "We know of no persons doing business in New York who will give you any more than \$15 worth of watch, jewelry, or anything else, for \$15." Not only were we overrun with these inquiries, but the Police and Post Office authorities had similar applications from all quarters, concerning "Russell & Co.," and their allies, "Hetherington & Co." Though "Russell & Co.," and the others, were watched, so carefully were their plans laid, that the officials could find no grounds for arrest. People at a distance complained, but unless they could make a complaint here, in the courts, in person, nothing could be done; and so the matter went on. Recently, Anthony Comstock, Special Agent of the Post Office Department, has convinced the Department that these parties were using the mails improperly, and his presentation of the case induced

THE P. M. GENERAL TO ISSUE A MOST STRINGENT ORDER, a part of which reads: "I do hereby forbid the payment by the Postmaster of New York City to the said Elias H. Elias, or to any person whatsoever of any Postal Money Order, drawn to the order of Russell & Co., the name used by said parties in the conduct of said scheme." In consequence of this order a large number of registered letters and Postal Money Orders have already been returned to their senders, who, if sensible, will thank the Postmaster General that they have been able to get their money back. It has long been suspected that Russell & Co. was only another name for Elias, and other well known operators in similar schemes. An assertion to this fact was made some time ago in a sensational article in one of the daily papers, but accompanied by no proof; but it appears that the Postmaster General is convinced that Elias is at the bottom of this—one of the most ingenious swindles of the day.

SEED SWINDLES ON FARMERS

are now as numerous as ever, and so important as to require a special article, which we hope to give before seed time comes. We are as desirous as any one can be, of bringing to the notice of our readers every novelty of real value, or which promises to be useful. Three are at present offered under new names, and names likely to deceive, very old plants. If these have any value at all, it is very local and limited, and if the seeds were offered at all, it should be under their proper and well known names. These

WONDERFUL AGRICULTURAL SEEDS

have of late been offered by heretofore unknown dealers in obscure towns in Tennessee, Michigan, and other Western States. Of course it is no prejudice to a good thing that it should have an obscure origin, but the things thus offered are either not good, or are offered under names likely to deceive. Thus "Ivory Wheat" is no wheat at all, but the old Durra Corn, a form of which is offered as "Pampas Rice," while it is no more rice than it is wheat. The "Diamond Wheat," which is offered with much flourish of names, including "Montana," and other kinds of "Rye," is, as we shall show at another time, one of the oldest grains in cultivation. So the "Hulless Oats," as "old as the hills," every now and then turn up as the basis of a disastrous swindle. The "Durra Corn," the "Polish" (though now called "Diamond Wheat," and by many other names), Wheat, the old, very old, "Hulless Oats," all these, almost as old as agriculture itself—many have their uses, but to introduce them as novelties, or under new names, shows, on the part of those who advertise them, either

IGNORANCE OR FRAUDULENT INTENT,

and so far as the purchaser is concerned, it makes no difference which. Let every farmer and gardener be assured that unless a "novelty" in the way of field or garden seeds has the endorsement of some agricultural paper—is either commended by the editor of the paper, or by some correspondents, whose accuracy the editor endorses—let him be sure that he can afford to wait, or if he tries the thing at all, let him do it on a scale so small that failure will be of no serious detriment. In beginning our war against Humbugs, for the new year, we have given prominence to one, the influence of which for evil is shown, by our correspondence, to be the most widely extended, and another month propose

to pay attention to others, which, operating in a smaller way, are none the less pernicious. One of the biggest of

THESE SMALL HUMBUGS,

is one E. C. Abbey, "M. D.," of Buffalo, who advertised everywhere his "Puzzle Picture," the Toll-Gate."—Very innocent indeed is the advertisement.—We saw it in a religious paper, edited by a distinguished "D. D.," whereupon we sent the good Doctor of Divinity the "Toll-Gate" itself. The advertisement did not appear in that paper any more. Now this same Abbey advertises in religious and other family papers his "puzzle picture" of "THE TRUANT BOY," and, like the "Toll Gate," it is a (so-called, but very poor) "puzzle picture" on one side, and on the other side, we have just such an advertisement as went with the Toll Gate, and one which no parent would wish his son to read. The card of the rascal says:—"This picture is 'intended to introduce a far more interesting Book,' (the italics are his), containing new truths never before in print"—* * * with portrait of the author, (Oh!) It tells all about Manhood, Womanhood, Sex, Beauty—well, we can't, in decency, tell the rest. Now you gentlemen who publish religious and family papers, won't you, in the interest of common decency and morality, just send and get a copy of the "Puzzle Picture" which you advertise to the young of both sexes, and who suppose that nothing improper can appear in your pages. Won't you, we say, send and get one of the things you advertise. You will get something which you *dare not* read aloud in your family circle. Yet you invite all to get the vile thing.

IN THE MEDICAL LINE

are several things that must have attention soon. If you get an alarming circular, headed "Diphtheria Suffering and Death," from Honesdale, Pa., put it in the fire, and read what is said about diphtheria on page 25.

THINGS GOOD TO LET ALONE

are a "Wonderful Tea Importing Co.," in Cincinnati.... Likewise the various concerns which are after owners of property in England, Scotland, and Wales, of which, no doubt, "the rightful heirs" are perversely keeping the many Smiths, Joneses, and Robinsons out of.... Also, those Telegraph Schools, which promise good situations at high salaries, are to be investigated before paying for "scholarship."... If any one has money to throw away, there are still several "Mining Companies," notwithstanding the inglorious fizzle of the "Silver Mountain" concern, that will take in all that may be offered.... We can well understand the indignation with which a gentleman doing a respectable business in Connecticut, opened a letter addressed to his recently deceased father, informing him that he (the father) had been recommended to the writer as a "reliable party" to assist in the "disposal of some goods," which "goods" were counterfeit money. If the son had kept the run of our exposure of this worst of swindles, he would have known that no one was safe from vile proposals, and that the few who were caught were most deservedly fleeced.

A Personal Convenience.—We do not know what it is called, but it was sent us by J. S. Birch & Co., No. 38 Dey St., who have so long advertised their "Universal Watch Key" in our columns. The article is about the size of a coat button, and fastens to the vest like a breast-pin. It has a cord, and at the end of the cord a hook, to which the eye-glasses are attached. The cord is taken up within the button by a spring, and the glasses are ready for use, or out of the way in an instant, by the proper management of this very clever contrivance.

The Value of Starch Factory Refuse.—"F.," Ashland, Me. The "slump," or waste from starch factories contains all the substance of the potatoes except the starch. If this waste, along with the vines, is returned to the soil, it is difficult to say why potatoes may not be raised many years in succession upon the same field, without exhaustion. The starch is wholly carbon and hydrogen, which are plentifully supplied by the atmosphere and by water, there is probably a loss of some (but very little) nitrogen in the finer portions of the potatoes which escapes with the waste water.

What Is a Cord?—"J. M. E.," South America, Ill. There are 128 cubic feet in a cord of wood, or a cord of manure; a cord being a heap 8 feet long, 4 feet high, and 4 feet wide. A cord foot is a 32nd part of a cord—that is, it is a heap of wood having a face one foot square, irrespective of its length. A cord of stove-wood consists of 32 cord feet, and if the wood is one foot long, would be a pile 8 feet long, 4 feet high, and one foot wide, containing 32 cubic feet; if the wood were 2 feet long it would contain 64 cubic feet.

Shrinkage of Grain.—The loss of weight and bulk of grain in process of drying, is from one-fifth to one-fourth for corn, and one-twelfth to one-tenth for wheat, and other small grains. In addition to

this shrinkage there is the loss by the depredation of vermin, and that of interest on the value until the grain is sold. The whole amount of loss is a serious item, but one that rarely enters into the farmer's calculation when he determines to hold over his grain until the spring, or next summer, for an advance of a few cents a bushel. Instead of gaining by this, he very often loses, and the loss may easily be figured up to from one-sixth to one-fourth of the crop, or its value, when harvested.

Ringbone.—M. W. Patterson, Clark Co., O. The only cure for ringbone is blistering. The hair should be shaved off from the part, and some common blistering ointment rubbed in. When the blister acts, the part should be washed and sweet-oil applied.

Apples Rot upon the Trees in Mississippi.—N. L. L. asks how to prevent it. The very first step will be to ascertain if he has varieties suited to his climate, and of this nothing is said. Northern varieties, as a general thing, do not succeed, but there is a set of fine Southern apples that do finely in his State. The varieties being all right, we should look first to drainage, and next to nutrition; if the trees are poorly fed, the fruit will complain.

Winter Oats.—"A. A. H.," Cumberland Co., Tenn., writes in regard to Winter Oats, that "they are not so hardy as Winter Wheat, although they are more extensively grown of late than previously." To test this matter, we have procured seed for one acre of these oats, and have sown them: if they succeed we shall report the fact in good season next year.

How to Manage a Farm.—"J. K.," Chicago. We have not space in any one number of the *American Agriculturist* to explain fully how a farm should be managed by one who knows nothing of the business. A pretty good idea could be gained by reading a whole volume, and carefully noting the Hints for Work, and the seasonable articles published every month.

Insects from Spain, sent by "H. G.," were crushed and in fragments beyond all recognition. Even for short distances it is necessary to send insects in a box or something which will keep them whole.

Is Meal Best Dry, or Scalded.—"J. E. W.," Frankfort, Ky. If the labor is not too great, it would be better to scald the meal, rather than to feed it dry. It is less apt to cause indigestion when scalded and fed moist.

How to Burn Lime in Heaps.—"E.," Athens, Ohio. Lime, where there is no kiln, may be burned in heaps, lain up upon a foundation of dry wood and made in alternate layers of wood and limestone. The heap is covered with sods, or coarse hay and earth, as charcoal pits are, and burned in precisely the same manner, except that the fire is made to burn briskly instead of smouldering; the lime is completely burned in three days. Lime may be spread upon the land to advantage in the spring.

When to Sow Orchard Grass.—"E. S.," Athens Co., Ohio. Orchard grass makes the best pasture for early use. It succeeds best if sown by itself on well prepared ground early in spring.

Coal Tar and Coal Ashes.—Coal tar is hurtful to shingle or board roofs, unless it is first mixed with some air slacked lime to neutralize the acid contained in it. Coal ashes have no appreciable fertilizing value.

Shorthorns and Durhams are the same. "J. A. T.," Georgetown, Mass. The Shorthorn cattle were first bred largely in the County of Durham in England, and near the river Tees. Hence they were called Durhams and Teeswater, as the case might be. In a few years they were spread all over England, and the name Shorthorn was given them to distinguish them from the formerly popular Longhorns, and stock that was not thoroughbred. When the Shorthorn Association was formed, and a Herd-book was established, the old names were dropped, except by those who were not well informed about the matter. A few of these keep the old names yet, which leads to confusion.

"Fern Leaf Mottoes."—In these, ferns (which have no "leaves" proper), are made to work in a good cause. Their fronds, and parts of them, are neatly arranged to form such mottoes as "God Bless our Home," and to surround them with a border. Impressions of these, fixed by photography in black and white, form very pretty ornaments. They are sold in considerable variety, solely where they will aid in the work of both

foreign and home Missions. Particulars may be had of Mrs. J. R. Nicholas, Darby P. O., Philadelphia, Pa.

Catalogues Received.

The catalogues of seedsmen, nurserymen, florists, etc., are not usually ready before February. We give those that have thus far come to hand, placing them, as usual, in order not to give one precedence of another, in alphabetical sequence.

NURSERYMEN.

G. H. BANTA, Riverdale, Bergen Co., N. J., offers at the Glenwood Nurseries a general assortment of fruit and ornamental stock.

SAMUEL C. DeCOU, Moorestown, N. J., makes a specialty of small fruits, offering the latest novelties.

A. HANCE & SON, Red Bank, N. J., send both their wholesale and retail list of a full and varied stock, with many novelties and specialties.

R. S. JOHNSTON, Stockley, Del.—A general nursery stock, with several new peaches.

RANDOLPH PETERS, Wilmington, Del., at the "Great Northern and Southern Nurseries" offers a very large stock. He makes a specialty of peaches, and his list and its classification is an interesting study to all proposing to plant peach trees.

E. WARE SYLVESTER, Lyons, N. Y., sends an abridged but comprehensive list of fruit and ornamental stock.

SEEDSMEN.

WM. H. CARSON, 125 Chambers street, New York City.—Special circular describing the Egyptian or "Pearl" Millet, a new "Spiral Mignonette" and other novelties.

DAVID LANDRETH & SONS, Philadelphia, Pa., send their "Rural Register and Almanac," including a catalogue of the seeds raised and sold by this well known firm.

J. B. ROOT, Rockford, Ill.—The Garden Manual for 1878, and Seed Catalogue—the business of seed growing and selling being continued by Mrs. Root.

CHARLES SZER, Mount Lebanon, Col. Co., N. Y., is quite early with his "Shaker's Catalogue and Amateur's Guide to the Flower and Vegetable Garden." The catalogue is neat, full, and well illustrated.

E. WYMAN, JR., Rockford, Ill., is out with his catalogue of flower and vegetable seeds for 1878, the flower seeds predominate, and good cultural directions given.

FLORISTS.

WM. E. BOWDITCH, 645 Warren street, Boston, Mass., offers greenhouse plants and seeds.

L. B. CASE, Richmond, Ind., issues a "Botanical Index," quarterly, as a combined magazine and catalogue.

J. C. McCONNELL & Co., Jacksonville, Ill., have a very full stock of greenhouse and bedding plants, roses, bulbs, and florists goods.

HENRY A. DREER, 714 Chestnut street, Philadelphia, Pa., though perhaps best known as a seedsmen, sends a separate catalogue of greenhouse and other plants, showing that his stock in this line is very large and up with the time.

EUROPEAN CATALOGUES.

WM. BRYCE & Co., Glasgow (Scotland), and London (England).—A wholesale price list of vegetables and agricultural seeds.

LENAULT-HUET, Ussy, France, W. L. Ferris & Co., Poughkeepsie, N. Y., agents.—A general nursery catalogue, the English of which is very Frenchy, but the collection is a fine one.

WATTE, BURNELL, HUGGINS & Co., London, (Eng.), and Paris, (France). This one of the great seed houses of Great Britain, has now a branch house in France. Besides a wholesale price current of seeds of all kinds, they send a special list of Lilies, Gladioluses, (they have it "Gladioli") and other spring bulbs.

WILSON & RANKIN, Glasgow (Scotland).—A wholesale list of farm and garden seeds, very full in the grasses.

MISCELLANEOUS.

E. WEBSTER PECK, 110 Chambers street, N. Y.—Scroll saws, designs and materials, and ornamental iron work, including aquaria, ferneries, etc.

GEORGE SUCH, South Amboy, N. J.—A price list of cream-colored flower-pots, including very large sizes.

TRUMP BROS., Wilmington, Del.—Scroll saws of several patterns, and all the appliances and materials belonging to the art of scroll sawing.

RACINE HARDWARE MANUFACTURING Co., Racine, Wis., issue a handsomely illustrated catalogue of the ornamental and useful articles made by them.

MACHINERY, IMPLEMENTS, ETC.

C. & G. COOPER & Co., Mount Vernon, O., send their 42d Annual Catalogue, which indicates that this is no new concern. They make a great variety of agricultural and other steam engines, mills, and other machinery.

GEO. W. RUE, Hamilton, O.—A catalogue of his popular potato diggers, his seed drills, etc.

STEDMAN & Co., Aurora, Ind., offer a great variety of engines, boilers, mills, presses, and other agricultural machinery.

J. W. STODARD & Co., Dayton, Ill.—An illustrated account of the "Tiger" Snaky Hay Rake.

THE FARMERS FRIEND MAN'G Co., Dayton, Ohio, issue a neat pamphlet, giving a detailed description of their Grain Drill, and illustrate the peculiar excellencies claimed for their machine.

THE MANSFIELD MACHINE WORKS, Mansfield, Ohio, send illustrated catalogues of their Agricultural Steam-Engines, Saw Mills for farm use, Grist Mills, and other agricultural machinery.

THE STRAUB MILL Co., Cincinnati, O., make the "Gladstair" Corn Shelter of different sizes.

YALE IRON WORKS, New Haven, Conn., make the "Yale Steam Engine" in various forms, also the "Yale Vertical Mill," a grist mill of novel construction, the merits of which were explained in these pages several months ago.

Bee Notes for January.

BY L. C. ROOT, MOHAWK, N. Y.

Bees wintering in-doors should be left entirely undisturbed as heretofore directed. The hives out of doors should have their roofs or other covering removed during pleasant days, that the sun may shine directly on the hive, to dry up the moisture, and free the hive from frost. A board should be placed before the entrance to keep off the rays of the sun, so that the bees may not be induced to fly. In all operations avoid the least jar, if possible, as here, as well as in-doors, the most perfect quiet is essential to successful wintering.

Questions and Answers.

VENTILATION.—"How much upper and lower ventilation should the box and frame hives have, while in winter quarters, with the temperature at 45°?"—"If mats are placed over the frames, they will need no other upward ventilation. Box hives should have an inch hole in the top. An entrance so arranged that it cannot become clogged is sufficient for lower ventilation.

"SHOULD THE FLOOR OF A BEE CELLAR BE MADE OF CEMENT?"—Yes. It is, for several reasons, preferable to any other; and the sides of the cellar should also be cemented as high as the surface of the ground.

"WOULD YOU ADVISE A CONSTANT FIRE IN THE ROOM ABOVE A BEE CELLAR?"—Yes, unless the cellar becomes too warm in consequence.

"CAN LARVÆ SENT FROM ONE TO TWO HUNDRED MILES BY MAIL, BE DEPENDENT UPON TO REAR QUEENS FROM?"—"If sent under most favorable circumstances, it might prove successful, but I would much prefer larvæ taken from a hive nearer at hand.

"HOW EARLY IN THE SEASON CAN TESTED ITALIAN QUEENS BE PURCHASED?"—"As soon as the weather will admit of their being shipped. I would not advise securing them before May in this latitude.

"IS IT BEST TO FEED POOR COLONIES BEFORE COLD WEATHER SETS IN?"—"All feeding should be done before cold weather.

About the Microscope.

Plain Instructions about Using It, important to All, especially those Unaccustomed to handling Microscopes.

Among the many thousands who have it already, or will receive the *American Agriculturist* Microscope, it would not be surprising if a few should fail to derive from it the interest and instruction of which we know it to be capable. In deciding to supply our subscribers with the instrument, the difficulties that would be encountered through the inexperience of some of those who would receive it, were foreseen; to meet, and even to anticipate these, we prepared a descriptive circular to go with each instrument. This points out the method of making several convenient appliances, to increase the utility of the Microscope, and points out some of the various uses to which it may be put. Every person receiving the Microscope should not fail to go carefully through the six descriptive pages accompanying it, before attempting to use it. The following explanations will be specially valuable to many.

In our interviews with those who have called at the office for their Microscopes, and in noticing the manner in which they handle them, we find that our descriptive article does not entirely meet the case of those who have never had occasion to use a microscope of any kind, and we find that there are many such, and even those quite unfamiliar with the uses of an ordinary magnifier. It is necessary, then, to give even more elementary directions as to its use, than those given with each instrument.

The Microscope was described in detail, with illustrations, in the Dec. Number of the *American Agriculturist*.

This is for the aid of those entirely inexperienced, and we will suppose that the Microscope comes (as in many cases it will) to an intelligent person who has never happened to see anything of the kind before, and who, if he ever chanced to look through a magnifying glass of any kind, never gave the matter any special thought or attention. He takes the Microscope out of the box, and

He Should First Examine Its Parts.—In the first place there is a base of hard rubber, which supports all the rest, and in the center of this base, covering an opening, is a round plate of glass, called the *Stage*. Attached to the base are two metallic *Clips*, or curved springs, and these hold down two *Slides*, or plates, of glass, with a perforated water-proof plate (*cell*) between them. These, the two plates and the piece between them, he may pull out from under the clips, and put aside for the present. There will then be the base with its

glass stage. From the base there arises an upright rod, upon which slide the *glasses* or *lenses*. Of these there are three, joined together, which may be turned about and moved up and down upon the upright, they may be used as one lens, or they may be separated, and each used singly. Between the lowest lens, and the middle one, is a flat plate of hard-rubber, having a round hole in the center. This is called a *diaphragm*, which will be mentioned presently. Engravings showing the Microscope will be found with the general description on page 34. Having noticed all these parts, and seen what the instrument is, the next thing is to

Learn How to Use It.—A microscope is to magnify something, and that something, whatever it may be, is called an *object*. For the present purpose, a little practice, in order to get "the hang" of the instrument; some fine print will answer as well as anything, and is everywhere at hand. The size, or kind of type in which this is printed is called "Nonpareil," and some of the same can be found in almost every newspaper. Having found print of this size, cut out a bit, say an inch square, place it on the *stage* of the Microscope, slipping it under the spring clips. Set the Microscope on the table at a window where there is full day-light, (not direct sunshine), or if at night where a good light from the lamp will fall upon the paper, and not be shaded by the hands or a hat rim. Separate the glasses so that only the upper, larger one will be directly over the *object*, which in this case is the scrap of printed paper; turn the other glasses to one side. Now bring the eye near the glass, and look down through it at the print. Perhaps it will be blurred and indistinct. If so, raise the glass, by sliding it upwards. Raise or lower the glass until you find the light at which the printed letters look the largest, and at the same time the most clear and distinct. This will bring the glass near, or quite, to the very top of the upright, as its length is adapted to this. Now you have found the proper *focus* of the upper glass. Observe, that you can, without moving the eye, see 6 or 8 lines of the print, and a corresponding width. The space that can be distinctly seen is called the *field* of the Microscope.

Some, when they look through a glass, put the hand over the eye not in use, and most persons close the eye. With a little practice, the mind learns to concentrate on the work of one eye, and the other takes care of itself.

Having noticed the print, and the imperfect letters, without lowering the glasses, turn away the upper glass, and bring the second one in its place over the *object*, and look at the print as before. Very likely the letters will appear indistinct, and to see them, as clearly as possible, it will be necessary to push the glasses down upon the upright a little. To get the *focus* of this glass, (which is necessarily lower than the first one), we bring it nearer the *object*. We see that it has a *shorter focus* than the other. It will be seen that the letters look larger, and, with the eye at that distance from the glass where they look the largest and clearest, but 4 or 5 lines of the print can be seen without moving the eye.

Now turn the middle glass away, and put the lowest one in its place. To get a clear view of the letters, this glass must be pushed down still nearer to them, they will look much larger, and only three of the lines can be seen.

By this trial of the three glasses separately, it will be seen that the longer the focus, the less the magnifying power, and the larger the field, or the more can be seen. The higher the magnifying power, the shorter the focus, and the narrower the field—points of importance to keep in mind. In these trials each glass has been used singly.

Let us now put all the glasses together, leaving the *diaphragm* out at one side, and use the three as if they were a single glass, putting them evenly over each other. To get the *focus*, so as to see the letters most plainly, the glasses must be pushed down much lower than with either singly—so that the lowest is within half an inch or so of the *object*. With this *short focus*, we shall expect, according to the principle just stated, to find a smaller field. You can now see distinctly only the letters of a single line. Then with the short focus and narrow field, the magnifying power should be much increased. See how ragged and broken the letters look, and the fibres of the paper are distinctly visible! With the glasses thus placed the letters of only one line are plainly seen, and but about three of these letters in the line. But the letters of the line above and below, appear in part, just their ends, and serve to take away the attention from those directly under the glass. Just turn the *diaphragm* into its place, between the lowest and middle glasses. This cuts off the view of the parts of the other letters, and they no longer interfere, while the three letters directly in view, appear much clearer. This then is the use of the *diaphragm*—to make the field smaller, and to cut off those objects which can not be distinctly examined.

In looking at the printed paper as an *object*, we keep the microscope standing on its base, the light falls upon the paper, and passes from that through the glasses to the eye.—We examine it as

An Opaque Object.—And this is the way in which the microscope will be largely used, as in the examination of Seeds, in the study of Flowers and Insects, and for many other purposes. We selected the print as an object to practise with, because it is something that every one can get without trouble, and if not so interesting as some natural objects, every one understands what it is, and with it can learn the handling, or

Manipulation of the Microscope. One of the first requisites in the use of this, as of any other microscope, is *patience*. Though quite as important, perhaps, is a real desire to learn whatever the microscope has to tell about an object.

After learning how to handle the microscope with opaque objects, those of another kind may be tried. Many things that one wishes to examine are of such a nature that they allow more or less light to pass through them. These are classed as

Transparent Objects, and are seen by *transmitted light*, or light which passes through thin substances, through the lenses of the microscope to the eye. It is well to examine most objects first as opaque, and then, if of a kind to allow of it, by transmitted light. Objects of this kind need a quite different handling from the others. Just at this season there are not many such objects that every one can get. Perhaps the wing of a common house-fly is as readily obtained as anything of the kind. In almost every house, a dead or dormant fly may be found in some corner, and its wing will make a pretty object. To examine this, the two glass slides are needed, without the waterproof cell between them. Clean the slides, neatly pull off the wing of the fly, lay it upon one of the glass sides, place the other gently upon it, and slip the two together under the metal clips, or springs upon the base of the microscope, and it will be held securely in place. To see this, the microscope is to be held up towards the light, which will pass through the glass stage in the base, through the fly's wing and the slides which hold it, and through the lenses of the microscope to the eye. The different glasses may be tried singly and in combination as directed for the printed paper. The same changes in the glasses, whether nearer or further from the object to arrange the *focus*; the same difference in the size of the *field* and the same (or even greater necessity, for), use of the *Diaphragm* as before, will be noticed—and we may add, the same *patience* and careful handling will also be needed. In using the three lenses together, there is a

Mechanical Difficulty.—The upright or rod upon which the glasses slide is in the way of the observer. This could not be overcome without at least doubling the cost of the instrument, and as one of the striking features of the microscope is its heretofore unheard of low cost, it was judged best to keep the price low, and submit to this slight inconvenience, which, after a short use, one soon learns to allow for, and does not notice—still, we think it proper to point it out, that it may be in mind when first using the instrument. All this about

The Mere Handling of the instrument seems necessary for those utterly inexperienced—and the examples selected are merely for the purpose of making one acquainted with it. The sheet that accompanies each instrument suggests various objects of interest, and it should be carefully studied through. With a microscope at hand, one soon becomes accustomed to subject a large range of articles to its scrutiny, and it will be found in frequent demand. The glasses of a microscope are often spoken of as

Powers.—A lens with a long focus and broad field, we have shown magnifies less than one with a short focus and small field, and the combination of three, with the shortest focus and most limited field magnifies more than either lens alone. The three lenses together are then the highest power of this Microscope, and the upper lens by itself is the lowest power. It is always well to examine an object with a low power first. This allows more of it to be seen, and one then knows what part of it to try with a higher or the highest power. Those familiar with microscopes, will look upon these detailed and simple instructions as superfluous. They are to such persons, who cannot understand how strange such a simple microscope is to the hundreds who may have never seen—much less tried to handle and use it. To illustrate how little such matters are understood by those who are entirely inexperienced, one friend wrote that he had looked through the instrument in every possible way, and "he could see nothing." This gentleman evidently supposed that the objects to be looked at would be with the microscope, and that, as with a kaleidoscope, the thing was all there and he had only to look in and see a sight. We send out the microscope, in part as an *educational agent*—useful for what it will teach about natural and other objects, but it appears that in some cases its educational influence will begin by making persons acquainted with itself, and the method of using it.—We will hereafter give simple instructions for preparing objects.

Building Homes.

Forty-Five Millions of People in our country want some kind of a house to shelter them. At least ten millions of these give considerable thought and attention to the style, comfort, and convenience of the dwelling, in which they eat and sleep, rear the family, and in which is passed all of the time of mothers and daughters, and half the time, more or less, of fathers and sons. Some millions of people spend at least half their lives in toilsome effort to secure their own homes. Very few have the practical architectural skill needful to plan and construct, or have constructed, the best, the most convenient, the most comfortable, and the most eye and taste pleasing dwelling that can be erected with the sum they can devote to this purpose. This fact has led us to endeavor to give in every number of this journal some plan and some suggestions that may help in improving the homes of our readers, and especially aid those who have houses to build. Recognizing in Mr. Reed an architect, who possesses the rare talent of "common sense," we have given this department mainly to his care, and have sent to him most of the contributions from our readers in this line. For three years past he has supplied to nearly every number of this Journal, some house-plan of his own devising, or one made up from the suggestions of contributors. These plans cover a wide range, from the lowliest \$300 or \$400 unpretentious residence, up to the costly, tasteful mansion. We do not commend all these plans, by any means, yet scarcely one fails to afford some useful new hint or suggestion. Those who have read them from time to time, must have noticed the many good ideas, new and old, which they have presented. The details in construction given, and the carefully prepared estimates of amount, kind, and cost of materials and labor, are of great practical value. Any one having a dwelling to construct, modify, or improve, would doubtless save ten or a hundred fold their cost, if, before deciding upon a plan, he should procure the past three volumes of this Journal, and read through all that Mr. Reed has written, and also what he will hereafter contribute. We hope that within a year to come, Mr. Reed will be able to combine and concentrate into a popular volume of convenient size and price, what has already appeared in these pages. In the meantime, those who want earlier information can obtain the past three Volumes, bound or unbound, if they have them not already. (See Publishers' notice, page 6.) We solicit continued correspondence, plans, notes, queries, etc., to be sent to Mr. Reed, as helps to make his contributions still more valuable, and as much as possible adapt them to meet the wants of the greatest number.

Science Applied to Farming.—XXXVII

Progress of Agricultural Science.—Cheap Fertilizers.

The number (37) of this article reminds me that I have been writing now three years for the *American Agriculturist* on topics connected with Agricultural Chemistry. In this time I have grown to feel, in a sense, acquainted and in sympathy with my readers. The letters they write are from almost every State and Territory in the Union, and some from foreign lands, the talks with those I meet, the keen interest so many express in the science whose simpler details I have tried to tell them about, the enthusiasm with which not a few have reported their success in putting into practice suggestions I have made, and, withal, the words of thanks and cheer that come as well from men whose mien tells of hard and homely toil as from those whose language savors of learning and air of wealth; these all assure me that to begin this the fourth year of my letters to them, no topic will please them more than the wonderful progress of science applied to farming.

Although,
"Science comes but slowly, slowly, creeping on from point to point,"
and though farmers are proverbially conservative,

yet agriculture is gradually coming into line with the other arts and industries in the march of modern progress, and making use of its share of the benefits of science. A proof of this, cheering as it is conclusive, is found in the wonderful growth of the Agricultural Experiment Stations. It is only a little over a quarter of a century ago that a few progressive Saxon farmers, seeing what chemistry was doing for other interests, firm in the belief that it would do no less for theirs, their faith confirmed by the examples of Liebig in Germany, Boussingault in France, Lawes and Gilbert in England, and some of their own number at home, but, at the same time, feeling the need of more accurate experimenting than they, as individuals, had the means or the skill to carry on, joined together, and founded, in 1852, in the little village of Mœckern, in Saxony, the first *Farmers' Station for Agricultural Experimenting*. An agricultural society furnished a farm; a private individual and another society contributed the necessary funds, the farm house was turned into a chemical laboratory, the farm supplied what else was needed. A young chemist of promise, the now famous Dr. Wolff, was called to conduct the work, and the Station was an accomplished fact.

The seed thus sown has borne marvellous fruit. The Mœckern Station proved so strikingly useful, that the government came to its aid and added to its revenue. The example proved contagious. Other Stations were started in Saxony, and then in other German States. Governments, agricultural societies, schools, and private individuals, united in founding them and contributing to their support. Soon the idea crossed the boundaries of Germany. The good work begun in France, throve in spite of the regime of Louis Napoleon, and under the Republic promises a successful future. In Austria, Holland, and Russia, like enterprises were undertaken, and are rapidly increasing. Italy, united under the liberal leadership of Victor Emanuel, found this one of the most efficient means of furthering her most important industry, and had, in 1870, one; in 1872, six, and has now sixteen Experiment Stations. Magnificent work in this direction has long been going on in England. Belgium, Switzerland, and Denmark, have joined vigorously in the movement, and, last of all, Spain has fallen into line with a Station started in 1876. There are, to-day, no less than 119 regularly organized Agricultural Experiment Stations in the different countries of Europe. Portugal, Greece, and Turkey, being the only ones without them.

Of these 119 Stations, over one-half have been established in the last six years, and 40 during the last three years. Prussia has 29, all Germany 66, and the other European States 53. Besides these, there are not far from 50 laboratories connected with universities, agricultural schools, or large estates, which, though not technically Experiment Stations, are doing the same kind of work.

It is a suggestive fact that among the earliest means adopted by the Germans after their war with France, to conciliate their newly acquired provinces of Alsace and Lorraine, by improving their condition, were, in accordance with the policy that brought them their great victory, the establishment at Strasbourg, of a University, and at Ruffach, of an Agricultural Experiment Station. That a large part of the pecuniary support of these institutions comes from farmers, is proof of their appreciation by practical men. The estimate in which they are held in the scientific world is indicated by the fact that all the larger German universities, and several of those of other European countries, have laboratories and other appliances devoted to agricultural research.

Experiment Stations in the United States are still in their infancy, but promise a brilliant future. Only two have as yet been successfully inaugurated, one in Connecticut, and one in North Carolina. Several of our leading Universities, Agricultural Schools, and Bureaus and Boards of Agriculture, have been doing excellent work in this direction, notably the Bussey Institution of Harvard University, the

Georgia Bureau of Agriculture, and various others. As I am informed by persons who have applied in person or by letter for information concerning the organization of the Connecticut Station, efforts, led by prominent agriculturists, are already in progress to secure the establishment of similar institutions in no less than eight other States, and steps are being taken in the same direction in several more.

What is the Cheapest Commercial Fertilizer?

is an inquiry that I frequently receive. The most economical fertilizer for a given case is that which supplies, in the best forms, and at the lowest cost, the plant food which the crop needs and the soil fails to furnish. The requirements of different soils and crops are of course varied. In itself considered, that commercial fertilizer is the cheapest which furnishes the valuable ingredients at the lowest rates. Our State Agricultural Society had this subject canvassed with unusual thoroughness by offering at their fair a year ago last fall, prizes for those "fertilizers which, as actually sold in the State, are found, on comparison of the selling price with the actual composition as shown by the averages of the analyses made at the State Agricultural Experiment Station, to furnish the valuable ingredients in the best forms and at the lowest prices per pound."

The first prize, a Gold Medal, offered "for the Fertilizer which furnishes the largest quantity, at the lowest price per pound, of Nitrogen, Phosphoric Acid and Potash," was given to *No. 1 Peruvian Guano, Rectified*, manufactured by Hobson, Hurtado & Co., and sold by them and by C. V. Mapes. In the Judges' report, which was based, not

"upon the specimens exhibited by manufacturers or sellers at the State Fair, but upon the character of the Fertilizers actually sold to the Farmers of Connecticut, as shown by analyses of a large number of samples collected from various places where they were sold," they "take occasion to say that we deem the plan adopted in the preparation and sale of Peruvian guanos, particularly the 'Rectified' and 'Guaranteed' brands, worthy of special commendation, in that the prices at which they are sold are based upon the analyses as guaranteed upon each package, each pound of the valuable ingredients being rated at a certain price, instead of the usual way of selling by the gross weight irrespective of the relative proportions of the valuable and the comparatively worthless ingredients. It is both fortunate and suggestive that the plan, which is the most rational and just one for the sale of commercial fertilizers, should have been adopted for an article of such leading importance in our agriculture."

The prize for ammoniated superphosphates was awarded to Russel Coe; that for superphosphates without nitrogen, "plain superphosphates," to H. J. Baker & Bro., and that for fish manures to the Quinipiac Fertilizer Co. The Stockbridge and Matfield Fertilizers received honorable mention as being what they were claimed to be. Since this report was made, a good many more fertilizers have been analyzed at our laboratory. Indeed, during a little over two years past not far from 300 samples of commercial fertilizers, comprising nearly all of the more important kinds sold in this part of the country, have come to my hands for analysis. Among these were 15 samples of Peruvian guano. The composition of these averaged, on the whole, better than was claimed. Taking into account both quality and price, no other fertilizers have been seen at our laboratory, which, as a class, taking into account both quality and price, furnish the valuable ingredients of plant food so cheaply as Peruvian guano.

Wesleyan University, Middletown, Conn.

Ogden Farm Papers.—No. 95.

BY GEORGE E. WARING, JR.

Whatever may be the future experience of the Ogden Farm enterprise, of one thing I am quite sure: that I shall have no duty in connection with it so distasteful as the writing of this paper. Henceforth—having learned wisdom by experience—I shall make no more promises. In the enthusiastic anticipation of a brilliant success, I promised, eight years ago, to tell the whole story of my farming, with full and entire frankness. I have left myself no loophole for escape, and must be as good as my

word. Moral: Be careful what you promise, that you may escape the need for doing what you would gladly avoid.

I have thrown my only sheet anchors to windward, in giving an account of my successes in the making and selling of butter, and in the breeding and selling of Jersey cattle. However good these are, they will not keep me from drifting on to the lee shore. Wind and tide set too strong that way, and I can only own up to a most ignominious failure in attempting to make a profitable operation of reclaiming a worn-out farm, by the application of the best modern improvements.

There is one office to be performed by this story, which will be of value to a very large class who are known as "gentleman farmers," for they are subject to the same temptation which undid me—the temptation that comes of having too much money. Mr. Tyler, my backer, entered into the scheme with a really growing enthusiasm, and strewed my road with roses. Year after year, his only anxiety seemed to be that not enough would be done. No improvement could be suggested—by my tongue or by his own fancy—which did not produce, without stint, what ever money the improvement might need. His boundless liberality, from the very start, has been equalled only by his entire kindness, and manliness in accepting the final and direful result. My one great consolation, in reviewing the whole matter, is the feeling that the cordial personal relations which have always existed between us, have suffered nothing from the strain which our failure has put upon them.

I have given ten years' services for ten years' most valuable experience; he has given a great deal of money for temporary hopes and satisfaction, followed by an assurance of failure and disappointment. The account is not even—nor can I make it so, however much I may yet accomplish for his son and successor.

To come down to details, I give the following figures:

Our total outlay has been.....	\$125,017 18
Divided as follows:	
Farm and Buildings.....	30,202 29
Labor.....	16,892 72
Implements.....	5,096 08
House Expenses.....	9,102 06
General Expenses.....	8,978 38
Feed.....	28,103 46
Manure.....	2,144 32
Seeds.....	513 29
Books.....	318 58
Live Stock.....	20,551 05
Produce Sold.....	3,114 85
Against this we have the following credits, amounting in all to.....	106,952 62
Divided as follows:	
Farm and Buildings, (estimated value),	25,000 00
Live Stock Sales.....	32,531 80
Live Stock on hand, (estimated value),	13,299 00
Produce Sold.....	23,321 82
Implements on hand, (estimated value),	1,500 00
Produce on hand.....	1,200 00
Good-will.....	10,000 00

This is the best estimate that I can possibly squeeze out, and it shows a deficiency of \$18,024.56, to say nothing of a very large amount of interest, which, on the whole, it would not be fair to include; for the naked fact is that, so far as money has been lost, it was lost when it was spent, and there would be no more reason in calculating interest for the period of our enterprise, than for calculating it henceforth forever. The case is bad enough as it stands, and it is not worth while to aggravate it by considering money which would have been paid from profits if profits had been realized.

Concerning the estimated assets given above, there is only this to be said:—The farm and buildings have cost more than they are appraised at, and there has never been \$500 spent on any ornamental improvement. We did spend some \$2,000 in an extension of the barn, and in a poultry-house, which have not much practical value. The land was considered cheap at what it cost, \$7,738. Its draining could now be done for about \$5,000. The buildings would now cost (the necessary ones, including the very fine barn) at least \$9,000, and the removing of interior fences, road-making, grading, etc., would be cheap at \$1,500. This leaves \$1,772 to represent

the increased fertility of the land due to the cultivation and seeding down that it has received, and to the enormous amount of manure added to it by the consumption upon it of all the crops it has grown for 10 years, and of our \$25,000 worth of purchased feed. The value of the live stock—as was stated in last month's paper—is made at fair selling-rates, and it could be closed out at the price within a year, paying its way in the meantime. The item of implements I might fairly place much higher. Produce on hand, (Sept 6), I lumped at the equivalent of 60 tons of hay at \$20 per ton—it amounted to more than that.

The remaining item, "good-will," I have put at \$10,000. I consider it worth that, under the most unfavorable circumstances. If I owned the farm to-day, and intended to follow the same line of business, I would not sell our reputation for a larger sum, for it would take years of hard work and volumes of successful writing, to replace it. A new comer, unknown as a dairyman, and as a breeder of Jerseys, could well afford to pay more than \$10,000 to be placed in the present position of "Ogden Farm," in the estimation of the public. On the whole, I consider my column of credits—footed up \$106,952.62—to be fairly constructed.

The practical question in connection with the whole matter is, whether it would now be possible to take up the enterprise—farm, stock, and good-will—and carry it on in such a way as to make a profit on this large valuation. As an ordinary farming operation, it certainly would not be possible. It would call for a net revenue, over all charges of every kind, of about \$6,500 per annum. But it need not be regarded as an ordinary farming operation. The aim should be to extend the business of buying and selling, and breeding Jerseys to the utmost capacity, not only of our 73 acres, but of such land as we could hire in the neighborhood, until we were in a position to supply any number of animals that might be called for by the constantly increasing demand. The utmost practicable extension should also be given to the production of butter, and its sale at a high price. Managed in this way, I think that a business might be done which would warrant the use of even a much larger capital; and it is to some such system as this that we must now look for success. My experience as Secretary of the American Jersey Cattle Club, enables me to form an estimate of the extent of the business. The "transfers of ownership" average about 2,000 animals per annum; and probably three-quarters of this number are original sales, the remainder being only records of old transactions. Most of these sales are probably made at prices at which it would not pay us to compete for them, but the demand is already very large for really first-class animals at profitable prices, and it is constantly increasing. There is a good field now, and it is steadily extending, for any breeder of first-rate reputation.

However, let us not speculate as to what may be done in the future. It will be better to wait, and tell in the future what has been done in the past—only let it be borne in mind that my *promising* days are over. If I make a success, I shall probably be willing to brag about it; if I make another failure, my pen will be otherwise engaged.

I have hinted above that "gentleman farmers" may find food for reflection in this account. I know the class pretty well. They have made their mark in all parts of New England and the Atlantic slope of the Middle States. Expensive, and often fanciful farm buildings, walls built for the sake of getting rid of stone, artificial land founded on piles of artificial rock-work, expensively drained swamps, which refuse to stay drained, and all manner of cash-sepulture, constitute their sign-manual, and one need only drive through any hundred miles of the region described, to become amazed at the vast sums of money—earned in other ways—which have been, and still are being, irretrievably lost in the attempt to gain credit and satisfaction in "Improved Agriculture."

We hear of this man, and of that, who is carrying on his fine farm "on strict business principles," and who is making a great success. Basing my belief on my experience, I fancy that their successes,

as a whole, will not often bear the searching scrutiny of the slate and pencil. Success in *items* is frequent. The bare statement that we started only ten years ago, with a wretchedly poor little farm, with no reputation, and with no experience in breeding or in dairying, and have sold our \$20,000 worth of butter, and have made a profit of over \$25,000 on our live stock, would mark us as most successful farmers. If we had kept no account of our outgoes, we should fancy ourselves champion Improved Agriculturists, whose business principles have been of the strictest and most successful sort. But we did keep accounts of everything, and they are here spread out before the triumphant gaze of the average reader. The rules of the English telegraph service will not allow a man, in a despatch of his own writing, even to call himself a "duffer." Let me take advantage of the amenities of the agricultural press, and refrain from naming my own obvious qualities. The impression under which I am now laboring is, that I cannot, in any system of strict terminology, be designated as an entire success.

At the same time, I have enough fight left in me yet to wish that I might measure trial-balances with some who may fancy themselves my betters. Look at my labor account; nearly \$1,700 a year—added to a charge for board of over \$900 a year—yet everything like draining, wall moving, road making, etc., is covered by the item "Farm and Buildings." I have never hired men because times were hard, and they needed help; I have never paid high wages; and I have always had long hours. I have done no fancy work of any sort—have even been called untidy, and have acknowledged it. In spite of all this, the whole of the large sum made on live stock, has gone this road. Look again at the amount spent for "feed," (including hired pasture, but none of the products of our own soil). It has swamped our total butter sales, and more than enough more to pay the original cost of the farm. Then, too, that horrible sum on "General Expenses," little odds and ends like postage, and horse-shoeing, and harness mending, and all manner of extras, it has run up to a sum nearly equal to the cost of boarding hands whose wages were more than \$16,000. The necessary conclusion seems to me to be that the steady and inevitable outflow of money required in carrying on a farm on anything approaching a "grand" scale, is more than the business can stand, even with the advantage of exceptionally high prices. Such farming as we have undertaken can not pay, unless it is done on a much larger or on a much smaller scale—small enough for the farmer and his family to do most of the work, or large enough for the commercial element to support the industrial element.

That Ogden Farm offers at least equally valuable hints to the farmer who carries on his own place very largely with his own labor, and who has only sufficient capital to carry it on in a small and careful way, I think no one who has followed its operations, as detailed in these papers for eight years past, will question. We seem to have made it very clear that to manage a small farm as one would manage a large factory, is not profitable. But, incidentally, there appears ample evidence that the small farmer may profit very much by an improvement of his processes, and by getting a reputation for producing only goods of the best quality.

We have had exceptional advantages, and have been able to get higher prices than a small, single-handed farmer could get under ordinary conditions—but, thus far, our advantages have cost more than they have come to. Every butter-making farmer in the country, even if he keeps but a half dozen cows, may, if he will keep good Jerseys, or breed to a good Jersey bull, and raise his best heifer calves, soon put himself in a position to get an increased price on his butter, and this increase will be all profit. If he improves the quality of his cows by crossing with Jersey blood, he will be able to get an extra price for his surplus, if sold only to his own neighbors. If he breeds a good quality of Registered Stock, he can depend on a good sale for his increase, at very remunerative prices. I instance these two items because they are the ones in which I have had experience. The same result would follow equal care in any other kind of stock

raising—or in seed raising. To do what is done in the best way that can be afforded, and to send to market the very best class of goods that can be produced, seems to me the means by which good and prudent farming is to be made profitable.

I have a theory that if I had begun with a good farm (costing much more at the start) I should

its being obscured by shrubbery and trees, which are indispensable accompaniments of a properly developed homestead.... **Cellar**, (fig. 2.)—Height 6½ feet. It has three windows, an outside entrance, and stairway leading to the kitchen above.... **First Story**, (fig. 3.)—Height of ceiling 10 feet. The accommodations, consisting of five rooms, a pantry, and two closets, are adapted to a good sized family. The Parlor and Kitchen are the principal rooms, and occupy the middle portion, their sides being protected by other rooms, and, having the fire-place between them, they are easily warmed. The device for heating described last month, would serve admirably in this house. Two Bed-rooms adjoin the parlor. Many might choose to have double doors entering the bed-rooms, to allow all three to be used together occasionally. This would not preclude the use of the smaller ones as bed-rooms, or, if preferred, as a sewing-room and a library. The Kitchen is the largest room, with doors leading to the pantry, bed-

gradients are simply fresh burned finishing lime, using the lumps only, and unrendered beef suet. It is necessary that these parts be kept in lively motion while dissolving, or they will be entirely

Fig. 1.—ELEVATION OF FRONT OF HOUSE.

have shown a better result—but there is no use now in thinking of “what might have been.” The ease with which I could get money, and the confidence I reposed in “strict business principles,” would probably have swamped me in the Garden of Eden.

Country House, Costing \$750 to \$1,050.

BY S. B. REED, ARCHITECT, CORONA, LONG ISLAND, N. Y.

These plans represent a commodious dwelling house, constructed with especial regard for economy and utility, and they will be appreciated by those desiring to provide a comfortable, permanent shelter for home by the use of limited means.... **Elevation**, (fig. 1.)—In preparing plans for “low-priced” houses, the simplest outlines are indicated. Having to combine usefulness and small outlay, there can be no latitude for architectural display, beyond mere matters of accommodation and completeness. The exterior of this example fairly expresses its domestic purpose. The breadth

room, parlor, stair-way, and the rear entrance. The outside or entrance doors may be protected in severe seasons by storm-doors hung to open outward, with loose joint butts to allow of their ready removal. The rear veranda is similar to the front one shown on the elevation.... **Second Story**, (fig. 4.)—The front portion only is finished, with ceilings 8 feet high, and is divided into two chambers and four closets. The rear portion is left unfinished to be used as an open garret. The space above the ceiling of the finished portion may be floored over with boards, to serve for storage of quilting-frame, trunks, etc.... **Construction**.

—The excavations for the cellar are 4 feet deep. The foundation walls are of broken stone, laid in mortar, and show 2 feet above the earth grade. A strong girder resting on large posts, or columns of stone or brick, supports the center of the building. In setting the girder, it should be elevated from ¼ to ½ of an inch in the center, rising gradually from each end, to allow for settling, which invariably occurs from shrinkage of the interior frame work. The timber for the frame work is indicated in the estimates below, and is substantially framed together. All the outside studding is halved over the principal timbers, to prevent vertical shrinkage from affecting the exterior covering of the side walls. The exterior covering is of lath and plaster, as follows: all cornices and other dressings, and the roof should first be completed—and all window and door frames set and cased. The outside frame should then be thoroughly lathed outside and inside. All this is to prevent jarring or pounding on these parts during the application, or setting of the plaster. The plaster is made in the usual manner of fresh burned lime and sharp sand—with half a bushel of hair to each barrel of lime used, and allowed to lay two weeks to insure a thorough slaking and permeation of the lime. It is then applied in two coats—the first a “scratch,” the second a “browning.” The surface is floated with a “dabby,” (not trowelled.) After having stood a sufficient time to become dry, the whole is covered with a preparation called “Sterate of Lime,” using an ordinary whitewash brush. The formula for making this sterate of lime, (known only to a few who have treated it as a secret), is here published for the first time, and will be understood by those familiar with the operation, and of slaking lime. The in-

Fig. 3.—PLAN OF FIRST FLOOR.

destroyed by “burning.” The usual process is to sink a large barrel, having an open end, two feet in the ground, pounding the earth around to make it firm. An upright piece, 4 inches in diameter, and 6 feet long, is set upright in the centre of the barrel, and held in position by cleats at the bottom and top, leaving the upright free to turn. Arms are put through the upright within the barrel, and a cross-bar or lever is attached to the upper end—the whole making an apparatus similar to a “clay-mill.” One bushel of lime, 20 pounds of suet, (chopped fine), and a barrel of boiling water are provided—and while one works the “mill,” another feeds alternately lime, suet, and hot water. This quantity of material, costing about \$2, will make a full barrel of the preparation. Any desired shade may be afterwards given by adding stainers. This mixture is applied while hot—two coats being necessary to insure a thorough covering. This will also be found a valuable preparation for covering exterior brick or concrete work. It is impervious to water, and will outlast any of the paints prepared for such purpose. All other information concern-

Fig. 4.—PLAN OF SECOND FLOOR.

ing the finish of this house may be inferred upon a careful study of the following estimates:

Estimate, cost of materials and labor:

95 yards excavation, at 20 cents per yard.....	\$ 19.00
1062 feet stone foundation, at 15 cents per foot.....	159.30
24 feet stone steps and coping, at 28 cents per foot.....	6.72
2000 bricks in chimneys, laid, at \$12 per M.....	24.00
517 yards plastering, inside, at 25 cents per yard.....	129.25
130 do. do. outside, at 30 cents per yard.....	39.00
1850 feet of timber, at \$15 per M.....	27.75
2 sills, 3x8 in. 34 feet long.....	2 plates, 4x6 in. 25 feet long.
2 sills, 3x8 in. 25 feet long.....	2 perlines, 3x8 in. 15 feet long.
1 girder, 4x8 in. 32 ft. long.....	2 perlines, 4x6 in. 18 feet long.
4 posts, 4x7 in. 11 feet long.....	100 beams, 1½x8 in. 13 ft. l'g.
3 ties, 3x6 in. 34 feet long.....	
300 wall strips, at 13c. each.....	39.00
4 locust posts, at 30c. each.....	1.20
190 flooring, at 20c. each.....	38.00
216 shingling lath, at 6c. each.....	12.96
39 bunches shingles, at \$1.40 per bunch.....	54.60
3 cellar windows, at \$5.99; 12 plain do. at \$7.88.....	93.60
17 doors, at \$4 ea., \$68; 2 verandas, \$50 ea., \$100.....	168.00
Stairs, \$20; cornice materials, \$18.....	38.00
Closet finish & base, \$15; Nails, \$12; Cartage, \$20.....	47.00
Painting, \$10; Carpenter's labor, \$100.....	140.00
Incidentals.....	13.22
Total cost, complete.....	\$1,050.00
Omitting Cellar and Verandas would save.....	300.00
Total, after deducting.....	\$750.00

Fig. 2.—PLAN OF CELLAR.

of the front, the preponderance of horizontal lines, and the hooded roof, are each indicative of strength, and suggest its adaptation to rural situations. The satisfactory appearance of this house will greatly depend on its location. The best results would be obtained by placing it on a slight knoll, giving it additional apparent altitude. This would prevent

Head of a Shorthorn Cow.

We give herewith an engraving of a fine portrait of a head of a model Shorthorn cow. This is "Duchess Gwynne, 2d," one of the choice mem-

bers of the finely-selected and highly-bred herd of Earl Bective, of Underley Park, England. This cow is 8 years old, and has borne 6 calves. Her dam was sold in 1866 for \$315; in 1868, she was re-sold for precisely thrice this sum. In 1874, the dam was again sold for the sum of \$2,227.50. Two years later, her cow-calf was sold for \$2,650. The cow, whose head we here reproduce from the "Agricultural Gazette" (London), is a finely-formed animal, and an excellent feeder and milker. Her reputation as a breeder is such that three of her calves realized at the last Underley sale, \$6,250. The cow is, therefore, a very valuable piece of property to her owner. The head is a model, and shows the animal to be of the tempera-

ment that we look for in a good feeder and milker. There is about it the true character which belongs to her Duchess lineage, and the air of high breeding which is so attractive in the show or the sale ring. One can readily excuse a wealthy purchaser, who is attracted by these qualities, for bidding what we may truly call extravagant prices for such animals. In reality, the prices given are extravagant when considered under ordinary circumstances, but when considered as value given for scarce and desirable articles of luxury, comparable with fine and rare works of art, the extravagance no longer exists. These animals are, in reality, works of art, because they are produced by the most skillful and artistic breeders for the purpose of luxurious enjoyment, rather than for ordinary uses as producers of milk and butter, or beef. In such a case, the rules regulating ordinary intrinsic values do not hold good, and we should be careful to distinguish between the circumstances surrounding these fashionable families of Shorthorns, and those relating to ordinary serviceable animals, when we feel disposed to criticize the actions of purchasers of the former. In relation to this subject, it is, perhaps, pertinent to refer to the present depressed condition of the Short-

horn market. It would be a matter for regret were this valuable interest to be unduly depressed. To some extent, the present unsatisfactory condition is due to an unavoidable reaction from the excessive speculative activity of a few years ago. Speculation always injures whatever it may touch,

in this way, but it is certain that out of the present condition there will grow a healthy legitimate business, in which there will be money for all concerned; for the breeders of high-bred families of unusual value, and sought by wealthy purchasers; for the breeder of the plainer and more useful ani-

horns, when thus divided into two distinct branches, and kept thus separated, is one that has a certain future before it, and will undoubtedly increase in extent and importance. There is no reason why confidence should be withdrawn from it, because in the process of the necessary separation above in-

dicated, it is under a temporary cloud. The production of meat is destined, without any doubt, to be immensely extended, as the great western plains become covered with herds, and as the farms east of those become feeding places for finishing off the grass-raised cattle into mature fat beef, or into breeding farms for supplying pure - bred bulls to the graziers; and as all these together become purveyors to the needy people of Europe, as well as to our own rapidly-increasing population. The present nucleus from which the greater part of our future beef, and much of our milk, butter, and cheese, must come, exists in our pure Shorthorn herds, and to these we must look for the greater part of the means we shall use for

the future development of stock-growing. With such a future in prospect, the Shorthorn interest can not long remain depressed. Intending buyers could have no more favorable opportunity than the present.

A Remarkable Jersey Cow.

Authentic records of the performances of good cows are valuable. They not only show what may be aimed at by breeders, and farmers, who should

keep only the best animals, and breed from these with the greatest care, but such records show very clearly the vast difference there is between good cows and the common ones generally kept, and how much more profitable the best cows are than others. There have been recorded from time to time, in the *American Agriculturist*, the products of a number of more than usually good cows, and we have seen these records gathered carefully by agricultural writers as evidence of the value to farmers of such excellent animals. These records, therefore, have a certain value, and as from time to time we are authentically informed of the performances of extra good cows, we gladly publish them as information of both present and future interest.

We have been favored by Mr. Harvey Newton, of Southville, Mass., with a record of his Jersey cow "Abbie," from April 17th, 1876, to March, 1877, during which time she yielded 10,070 lbs. of milk, as follows: April 17th to 30th, 417 lbs.; May, 1,365 lbs.; June, 1,406 lbs.; July, 1,247 lbs.; Aug.,

HEAD OF SHORTHORN COW "DUCHESS GWYNNE, 2D."

mals, for farmers and graziers' use; and for the farmers and graziers who buy breeding animals on their merits, rather than for those of their ancestors of several generations back. A farmer or grazier can well afford to give for a yearling for breeding purposes the sum which it would bring for beef when mature, or for milk and butter when a cow; and this price would pay the breeder very handsomely. The so-called fashionable animals will always bring high, and, when judged by an ordinary standard, extravagant prices; but so long as spec-

JERSEY COW "ABBIE."

ulation does not run wild in consequence, there can be no objection to the enjoyment, by men of wealth and fine taste, of the satisfaction which comes from the possession of animals which are attractive for their beauty, and costly from their scarcity and expensive breeding. The business of breeding Short-

1,155 lbs.; Sept., 992 lbs.; Oct., 907 lbs.; Nov., 794 lbs.; Dec., 788 lbs.; Jan., 1877, 707 lbs.; Feb., 551 lbs.; March, 371 lbs. Total, 10,700 lbs. On April 15, 1877, she calved again. The butter produced within the year was 486 lbs.; besides which, milk and cream were supplied for family use. A portrait engraved from a photograph of this excellent cow is given on the preceding page.

Among the Farmers.—No. 24.

BY ONE OF THEM.

Old Novelties.

I wonder how many farmers feel as I do—a sort of repugnance to the very name *novelties*. After writing it above, to make it look less repellant I wrote *old* before it. In fact I have no thought of discussing new things, but only the fact that new things are all the time coming up, which, because their advocates claim too much for them, live the life of a nine-days'-wonder, and then die of over-exaltation. It generally happens that somebody has faith in them, and so they are kept alive in the warmth of some enthusiast's fancy or kitchen garden, waiting a subsequent resurrection and the recognition of their virtues. Possibly, like Cleopatra's Needle, they may be thought more of at the antipodes than at home, and, in fact, that is the way with many of our most valued crops. I met with Mr. James Salter, the other day, he had

A Chinese Yam

as large and long as a man's arm, nearly, which he had raised in the yard of his Brooklyn dwelling. He raises these yams regularly, and has done so ever since the plant was brought out with such a flourish of trumpets by Prince, of Flushing, fully 20 years ago. They furnish an abundant quantity of excellent food, of which the children are very fond—preferring it decidedly to any preparation of common potatoes. They are cooked by simply boiling—and of this they require very little before they become mealy and delicate, so that it is not alone the children who are fond of them. Mr. Salter plants some every year, and they occupy the ground two years, at least, then, by digging a trench by the side of the row, the tubers are taken out, and are long and large in proportion as they have been long in the ground. Although Mr. S. makes a planting by sowing the small "bulblets," or little tubers, which form in the axils of the leaves, in rows like beans, and thinning out the row subsequently, by removing the plants if necessary, yet he saves a year's time at least, by cutting off the upper end of the long tubers when he digs them, and setting that out at once. The form of the tubers, as is well known, is peculiar. They are club-shaped, the big end being deep in the ground, and the long, slender handle end, so to speak, being at the surface, and this is what is cut off and replanted.

The vine of the Chinese Yam is highly ornamental, it being somewhat like the Madeira vine, which is so popular, but prettier. Mr. S. has a farm in Connecticut, where more or less of it is regularly raised. Most of the best seed stores furnish the little tubers, and any one may readily add a new vegetable, the raising of which will give very little trouble, to the list of those now cultivated, and of which we may become exceedingly fond when it is generally cultivated. [By "raising," our correspondent evidently does not mean the lifting of the roots, or "tubers," as he calls them. The greatest obstacle to the culture of the plant is the difficulty in digging it, and on this account it can never become popular or profitable.—Ed.]

Lung Murrain among Long Island and New Jersey Cows.

It has been a well known fact that pleuro-pneumonia has been lurking in the "swill milk" stables of Long Island and New Jersey for years, and that now and then it escapes from its legitimate haunts and decimates the herds in the surrounding country, or in circumscribed districts. One of my friends among the farmers of the Island, called to-

day to ask what he could do to protect his herd of cows from the "distemper."

"Distemper," said I, "'cow distemper,' what is that?"

"The milkmen call it so," said he. "It shows itself by a cough, and by the cow standing with her back bowed up and her head down, and looking dull and stupid."

"That is something terribly like the lung murrain, or cattle plague, the pleuro-pneumonia, which was so fatal in Massachusetts in 1860, and was so vigorously stamped out by the State authorities, by killing and paying for every animal that had been exposed. How near is the disease to you now?"

"I don't know how near it is, but my neighbors have been inoculating their cows for it, by taking little slices of the lung substance of a cow which had the disease, and inserting them in slits cut in the tails of their cows, binding the inoculated ends of the tails up with a rag for a few days. As soon as it takes, the rags are taken off, and it makes a bad sore, but the cows do not have the distemper. Now I want to know if it will not do just as well to take some of the matter from these wounds, and introduce that, as to get a piece of diseased lung."

I could not answer that question from previous knowledge, but imagine that from the fact that pieces of fresh lung are always used, that the results are best when obtained in this way. The stump-tail cows of the swill milk stables gain their distinction from this cause, as the "distemper" travels up, sometimes involving their rumps more or less. I inquired if it were difficult to get the pieces of lung substance.

"No," said he, "they can be got at the slaughter-houses; the butchers know the animals that have the disease."

"What?" said I, "is it possible that this sick beef is killed and marketed?"

"Certainly. When an animal gets the distemper her owner turns her off before she gets it very bad."

In view of these facts do we not need

A Veterinary Inspector of Live and Dead Meat?

No doubt quantities of unhealthy and even badly diseased meat is sold annually in our large cities, and particularly in the group of cities around and including New York.

It is a fact for which we cannot be too thankful, that several of the diseases which are such scourges to the cattle of Europe and Great Britain, are much less virulent here. There is some quality in our dry atmosphere in summer, or in the zero-cold of our winters, which seriously interferes with the vitality of this very disease (Lung murrain) as also of the "Foot-and-Mouth" disease. This should not, however, lead us to be less careful, for some day a disease might be imported which would sweep off our herds as the lung murrain did those of south Africa, where it was introduced in 1855, and in two years had traveled 1,300 miles, literally sweeping the immense wealth of neat cattle off the face of the earth. We need a

Governmental Inspection of Incoming Cattle.

The people are deceived by certain requirements of the Government. Orders are issued to our Consuls abroad, as to certificates of health, etc., but so far as I know, and I certainly am in a way to know, a sick animal can be just as easily landed in New York as a well one, and I think easier. There is no barrier to the introduction of disease from foreign ports into the ports of the United States.

We had a wholesome scare two or three years ago about the Rinderpest, but like soldiers under fire, though the danger is as great now as it was then, we have long since given up the idea of protecting ourselves against it. What the results of an outbreak of the disease in this country would be, no one can tell. Like a fire in the woods, which now laps up the dry leaves, and stays only in some rotten stump or hollow tree, and again sweeps away miles of heavy timber, leaving nothing but charred stems and drifts of ashes, the coming disease may go by doing us little damage, or it may well nigh annihilate our herds. Are we ready for the experiment?

Hitherto the American system has left the pro-

tection of the people against the introduction of disease by water, to the several States which establish more or less efficient quarantine regulations at their various ports. The natural dread of "the pestilence which walketh in darkness, and the destruction which wasteth at noon-day," is such that people readily submit to any reasonable quarantine regulations. In fact, they submit to anything without questioning its reasonableness. It would not be so with regulations affecting the trade in cattle. Purely mercenary motives would be roused in men, and often no little expense incurred. Owners of cattle would evade the laws if they could, and the authorities in one State or another, to avoid expense, would wink at infractions, trusting to luck that no wide-spread evil would be the result. It is not a matter for the different States, but clearly one for the general Government to control with a strong, firm hand, administering the same laws on the coast of Maine as on that of Florida—on the Canada as on the Mexican frontier.

Money Made by Poultry Keeping.

It seems to me that the interest in poultry is increasing, and that more poultry keepers, instead of being absorbed by the insane idea that every one is going to get rich by selling fancy eggs at \$3 a dozen, or poultry ready to lay, at \$3 to \$5 a piece, are giving attention to raising eggs in winter, broilers in spring and summer, fat pullets in autumn, and capons in winter. In these products there is steady and sure profit. Of course a few will succeed as breeders of fancy fowls, but the number is limited, and they must have good judgment and keen perceptions, with persistence and perseverance.

Capon Raising

is a profitable branch of poultry culture which is not likely to be over done. The art of caponizing is easily learned. Mr. Rushmore, President of the Eastern New York Poultry Society, learned to practise it a few years ago, and last year raised a large number of these delicious fowls. He informed me that he lost not more than two per cent, and that there is no need of losing any if the birds are empty of food, and the operator has sufficient light to do his work well. Good fat capons will bring fifty per cent. more per pound than other fowls will sell for, and very large capons much more than that. The conditions for success are the possession of hens of a large breed, and the use of judicious crosses to produce quick growth, with hardiness of constitution and aptitude to lay on flesh. There is no doubt, I suppose, in regard to the

Advantage of Cross Breeding.

What breeds to cross, is a problem which has not yet been solved. I was much interested in learning of a series of experiments which Mr. Rushmore is planning to carry out next spring. They were suggested in a measure by an experiment tried this year with marked results. Asiatic fowls were bred pure, and also mated with Plymouth Rocks, which itself is a recognized cross-breed, but an established one. The result is that the cross-bred pullets and cockerels are several pounds heavier than the Asiatic pure bred ones, which have had equally good care, feed and other conditions of growth. Those cross-bred chickens instead of making a great growth of stilts at first, and subsequently laying a modicum of flesh and fat upon them, are always ready for the table, and profitable to send to market, after they are as large as quails. The first cross makes, as a rule, the greatest improvement upon the parent breeds, and a number of practical questions come up, in regard to the subject of poultry raising, with the view simply to produce the largest amount of meat which will bring the highest price in the market. For instance, as in the crossing of Brahmas and Plymouth Rocks, or any Asiatics with games, should the hens be of the larger breed, or the reverse? Which breeds crossed will develop the greatest early maturity? The greatest weight at the most profitable ages? The greatest weight and plumpness at the best market periods? Which make the best capons? There have been a good many half-made efforts to solve these and kindred problems, and I am glad to know that Mr. Rush-

more proposes to conduct some thoroughly well considered experiments on a sufficiently large scale to give data of substantial value.

Talks on Farm Crops.—No. 11.

By the Author of "Walks and Talks on the Farm,"
"Harris on the Pig," etc.

I have always had a prejudice against corn-fodder. I thought it was too bulky a crop in proportion to its nutriment. If fed green, we had to cut and draw 20 tons of material to get 3 tons of dry fodder of far less value than clover hay. I thought so long as we continued to plow under clover for manure, there was little sense or economy in raising a poorer article for food. But we find it is not always an easy matter to raise clover. In fact, for half a dozen years back, I have not had a really good crop of clover on the farm, and if it had not been for corn-fodder, I should not have been able to carry the desired amount of stock.

I raised corn-fodder because I could get the necessary food in no other way. Corn-fodder is a sure crop, and while by no means equal to clover hay, it is a good deal better than nothing. In fact, the longer I raise it, the better I like the crop.

I have raised it, not for soiling, but for fodder in winter. For this purpose, it is certainly a most desirable crop on my farm.

I have thought it might be better to plant a larger area of corn, using the grain for the pigs, and the stalks for cattle and sheep. But the corn-crop, in this section, requires too much work during the short and busy days of autumn to admit of a greatly extended area. But this objection does not hold in regard to corn grown exclusively for fodder. There is no husking. All we have to do is to cut the crop with a reaping machine, and bind it into bundles, and put it in large stooks for the winter. As soon as we get a good reaper and binder that will cut and bind the corn into sheaves, it is clear to my mind that there is no crop that we can grow in this climate, with the same amount of expense, that will afford so much food per acre.

"That may be all so," said the Doctor, "but the trouble is that the corn-fodder is not rich enough. There is more food per acre, it may be, than in any other of our commonly cultivated crops, but this actual food is mixed with too great a quantity of indigestible woody-fibre. If we could get rid of 500 lbs. of woody-fibre out of every ton of dry corn-fodder, the 1,500 lbs. that would be left would be worth far more, in my judgment, than the ton. If I had two acres of good rich land nicely prepared for drilling in corn-fodder, and was offered two varieties of corn, one of which was warranted to produce 6 tons per acre, and another 4 tons per acre, I would take the variety that would produce the smallest crop, in the hope that the 4 tons would contain as much, or nearly as much, actual food as the 6 tons, and if so, it would not only cost less to harvest it, but it would be far more profitable as a milk or flesh producing food than the six tons. "I do not say," continued the Doctor, "that we have varieties of corn that will afford a small yield of unusually rich fodder. But if we have, those are the varieties that we ought to grow. And our Experiment Station might do a worse thing than to investigate this subject."

"Prof. S. W. Johnson," said I, "has made some careful analyses of corn-fodder that are of unusual interest, and his remarks on the subject, like everything from his pen, are of great value."

"Very true," said the Doctor, "but they do not touch the real point. We are told how much corn-fodder was raised per acre, and how much nutriment the crop contained. But that is all. There is nothing to compare it with. It is good as far as it goes, but it does not go far enough."

After the Doctor had gone, the Deacon remarked: "Some people are hard to please. I do not know when I have read anything that pleased me so much as this same paper on corn-fodder."

"It is indeed a remarkable paper," said I. "Just such a paper as one would expect from the author of 'How Crops Grow,' and 'How Crops Feed,'

the two best books on scientific agriculture that have appeared during the last thirty years."

The fodder-corn, analyzed by Prof. Johnson, was grown by Mr. J. J. Webb, near New Haven, Conn. The variety sown was the Southern or Norfolk White. Three bushels of seed were drilled in per acre in rows two feet apart. Two crops were raised, one sown from 10 to 15 days later than the other.

The crop was cut September 1st. The yield of the early sown field was as follows:

When cut, September 1.....25½ tons per acre.
Cured in field, November 11.....5½ " "
In barn, February 8.....8½ " "

The yield of the late sown crop was as follows:
When cut, September 1.....27 tons per acre.
Cured in field, November 11.....4½ " "
In barn, February 8.....7½ " "

It is a curious fact, that 5½ tons of corn-fodder put in the barn, in November, should weigh 8½ tons in February. Prof. Johnson attributes it to the fact that the weather was very dry and fine in the fall, and the corn-fodder was exceptionally well cured in the field. But the winter was very rainy and damp, "and the loosely packed corn-fodder gained moisture."

"I have always known," said the Deacon, "that corn-fodder would get limp and soft in dark weather, but did not suppose that it would attract so much moisture."

"Cattle," said Mr. Strong, who has had considerable experience in feeding corn-fodder, "will always eat corn-fodder better if it is flung out on the barn floor in damp weather, or out of doors where the dew will moisten it. It will gather moisture like a sponge."

The following table shows the average composition of the two crops of corn-fodder at the time it was cut, Sept. 1, and also when well cured in the field, Nov. 11, and again after it had been loosely stored away in the barn until February 10. The composition of the fodder, when entirely free from water, is given in the last column.

TABLE SHOWING THE COMPOSITION OF CORN-FODDER.

	Fresh Cut, Sept. 1.	Field Cured, Nov. 11.	In Barn, Feb. 10.	In the Dry Fod- der entirely free from water.
Water.....	86.11	27.25	54.35	
Ash.....	0.79	4.19	2.64	5.76
Albuminoids.....	0.83	4.38	2.76	6.03
Fat, etc.....	0.25	1.31	.82	1.80
Cellulose.....	0.77	24.97	15.66	34.32
Carbo-hydrates (starch, sugar, gum, etc.).....	7.25	37.89	23.75	52.09

Good clover hay contains about 16 per cent of water. The corn-fodder contains, when fed out in February, 54 per cent—nearly 3½ times as much.

Good clover, when cut just as it is coming into blossom in June, contains 75 per cent of water, but we often let clover grow, until I question whether it contains 50 per cent of water. In other words, it is not as succulent as corn-fodder in our damp sea-shore climate in winter. The relish with which cattle and sheep will eat corn-fodder, after they have been fed for some time on dry hay, is doubtless due to the greater succulence of the corn-fodder. It is not because it is richer. In fact, the corn-fodder grown by Mr. Webb was not nearly so nutritious as good Timothy or clover hay.

Prof. Johnson gives the following table, showing the average composition of German hay and German corn-fodder, as compared with the American corn-fodder. The figures represent the amount of ingredients in 100 parts of the dry hay and fodder.

	GERMAN.		MR. WEBB'S.	
	Meadow Hay.	Red Clover.	Maize Fodder.	Maize Fodder.
Ash.....	7.7	7.4	6.7	5.8
Albuminoids—so-called flesh- formers.....	11.8	16.6	12.4	6.0
Fat.....	2.7	2.7	3.7	1.8
Cellulose—woody-fibre.....	29.9	30.1	29.3	34.3
Carbo-hydrates, (starch, gum, sugar, etc.).....	47.9	43.2	47.9	52.1

The German corn-fodder is quite as nutritious as good hay, but the American corn-fodder is decidedly inferior. This is doubtless due to the fact that

a large growing variety of corn was sown by Mr. Webb. Some of the stalks were 14 feet high. It produced too much woody-fibre. For corn-fodder, we want a small variety and rich land. A lover of celery prefers to grow the "Incomparable Dwarf" rather than the "Immeasurable Mammoth."

In the condition in which the corn-fodder was fed out in the winter, the average yield per acre was 8 tons of corn-fodder, containing an amount of absolute nutriment fully equal to 4 tons of good hay. So far as the yield per acre is concerned, therefore, corn-fodder is decidedly a profitable crop. The objection to the crop is, that it is too bulky—too innutritious. Such a crop as that grown by Mr. Webb could be used to advantage by a farmer who takes horses to board for the winter at so much per head per week. It will keep them alive and healthy. But for cows giving milk, or for young stock, or for fattening cattle, it is not rich enough. We want such animals to eat all the food they can digest, and such corn-fodder as that under consideration is too bulky. The stomachs of the animals will not hold all that could be digested. And in feeding such corn-fodder we must give the animals more or less grain or oil cake. It will pay well to do so, but it would pay still better to grow a richer and less bulky crop.

"It is easy enough," said the Deacon, "to grow a less bulky crop."

"True," said I; "but possibly not so easy to grow a crop rich in nutriment. This is the point that farmers and scientific men should investigate. If I was going to raise peas to cut green for hay, I would not select 'Champion of England.' The 'Little Gem,' or some other dwarf kind, would give a less bulky, but far more nutritious crop of hay; and it can not be doubted that the skill and intelligence which produced the dwarf pea, can produce a dwarf and highly nutritious variety of corn to be grown for fodder. These skillful plant-breeders will give us just what variety we ask for, and we should be careful to ask for that which is really good, and not for that which is merely 'big.' Then, when we have a fine, small-growing variety, we should sow early, on dry land, well and properly manured, either directly or indirectly. We should have a crop, say 6 feet high, and yielding 3 tons of the richest, and choicest, and most easily-digested 'maize hay' that could be cut and bound into sheaves by a reaper, at a cost not to exceed the cost of cutting and curing hay."

"There is one thing," said the Deacon, "in favor of sowing a small variety of corn for fodder. It will cure much more rapidly than the large varieties that have thick, long stalks. The larger the proportion of leaf to stalk, the quicker it will cure."

"That is very true," said I, "and I doubt not that we could cure the corn-fodder, or 'maize hay,' during our hot August or September weather, so that it could be put at once into the barn or stack, just as we do other hay. Such corn-fodder as I raised this year from a small early variety of our common corn, I think might have been stacked with perfect safety, especially if a layer of dry straw had been placed between each layer of stalks. I have tried stacking corn-fodder with greater or less success. I can see now where I have erred. We have postponed the operation too long. When the corn-fodder is well cured, the sooner it is in the stack or barn, the better. It will evidently attract a larger amount of moisture when exposed to a damp atmosphere; and it must be remembered that this external moisture is far more likely to cause the fodder to mold than the moisture or sap which is in the plants. The crop is rich enough in gum, starch, and sugar, to keep it from fermenting; or, if it is not, it ought to be, and would be, if we raised a small rich variety."

PRESENT VALUE OF COWS.—Public sales are a very certain index of values. The following prices realized for cows at recent sales in Eastern Pennsylvania, where there is not only good stock, but an active demand for animals at all times, will tend to show what ordinary farm cows are now worth. A sale of 20 averaged \$42.86 per head; 25 others brought an average of \$53.05 each, and another sale of 55 ordinary good animals made an average of \$52.

A Steam Pump for Irrigation or Domestic Use.

We have been using a steam pump during the

Fig. 1.—FRONT VIEW OF BOILER, TANK, AND PUMP.

past summer, by way of experiment, for irrigation and for pumping water for domestic use. The value of a practicable and cheap method of irrigation for market and fruit gardens, or for private gardens and lawns, and of a certain supply of water for domestic purposes is evident, and it is only necessary to be assured that the method is practicable and cheap, for a large number of persons to avail themselves of it. The pump we have been using is operated by an "Economizer" steam boiler of 2½ horse power, both of which are made by Porter Manufacturing Company, Limited, for Whitman & Burrell, of Little Falls, N. Y. The pump is operated directly by steam from the boiler, without any engine, and so far has worked in a very satisfactory manner. The pump is arranged either separately upon a frame not directly connected with the boiler, as shown at figures 1 and 2, or affixed to the boiler as at figure 3. In the first instance the pump is set upon a frame beneath a tank, which holds a supply of water for the boiler. This is fed directly and automatically by a simple provision of pipes; the water flows from the tank into the boiler as soon as the water-level in the latter falls below a certain point, therefore, so long as there is water in the tank, that in the boiler can never fall below a proper level. All that is necessary to ensure absolute safety in this respect, is to see that the tank is always supplied with water; the tank is provided with a water-gauge that this may be done

nections for carrying steam from the boiler to the pump and for the water supply. The rear view is shown at figure 2. We have had these engravings very carefully made, showing these connections accurately, so that any person may readily put them together. The boiler (A) and tank frame rest upon cross timbers, 4 x 8, to which they are bolted, the rear foot of the tank frame being exactly 11 inches from the rear edge of the supporting timber to which the foot of the boiler is bolted. The front of the boiler at the lower part, is exactly 7 inches in advance of the front of the tank frame. When thus placed, all the pipe connections furnished with the boiler, etc., fit accurately. The tank, B, is placed on the frame above the steam cylinder, C, and pump D, as shown in figures 1 and 2. The following references apply to figures 1 and 2 and partly to figure 3:—*a*, the safety valve; *b*, the steam-gauge; *d*, the steam pipe to the tank; when the water in the boiler falls below the mouth of this pipe, steam

enters, raising the pressure in the tank as high as in the boiler, and forces water from the tank through the water pipe *e* into the boiler; at *f* is the blow-off pipe by which the boiler is emptied; at *g* the exhaust pipe from the cylinder, which discharges into the smoke-stack; at *h*, *h*, is the steam pipe from the boiler to the steam cylinder, with valve; at *i* is the feed pipe to the tank connected with the discharge pipe from the pump, and shut off or opened by the cock shown in the engraving; at *j* is the discharge pipe from the pump; this is made either to connect with a rubber hose or with iron pipes, which convey the water to its destination; at *k* is the balance-wheel, provided with a handle by which the pump may be worked by hand to fill the boiler or tank before firing up; at *l* is the water-gauge, showing the height of the water in the tank; at *m* is the supply pipe to the pump; in figures 1 and 2 this is connected with a well near by; in figure 3 it is carried to a river, from which the supply is drawn. This pipe is 1½ inch in diameter up to the connection with the pump, the discharge being a one-inch pipe. At *n* is the waste steam pipe from the boiler. At figure 3 is shown the arrangement of the pump when affixed to the boiler. This is found to work very satisfactorily in drawing water from a river and forcing it through 1,200 feet of iron pipe to a series of hydrants, from which it is used in the irrigation of a large garden, the supply of several greenhouses, and other uses. Some persons will prefer this arrangement, which is economical of space, while others will choose that shown at figures 1 and 2, in which safety is made so absolute that the boiler may be securely left in charge of an inexperienced man for several hours, if the tank

is left full of water. The pump arranged, as shown in these engravings, has been used for the watering of a garden and lawn of 3 acres through 250 feet of rubber hose, and for the supply of a tank in the dwelling house, the hose being connected with the tap (shown in figure 4) upon the supply-pipe to the tank in the attic. The lower tap closes the connection with a hand force pump, (Blunt's Universal Pump), kept for use in case of accident. With a pressure of 20 pounds of steam, the water is forced through the hose and a ½-inch nozzle, and thrown 50 feet from the nozzle. After some months use of the pump, which is shown without any connections at figure 5, we find it to work very well, and to cost so little, that, to say nothing of its other valuable uses, it is more economical than the employment of a man once a week to fill a tank holding 1,000 gallons of water, by hand. The boiler is heated very rapidly, a little waste wood being sufficient to get up steam and run the pump for an hour or two. In a dry season, or even in the few dry weeks of spring, when garden crops are in a critical condition, the whole cost of the boiler and pump might be saved in the rescue of young plants from drouth, or in the rapid forwarding of their growth,

Fig. 3.—PUMP UPON THE BOILER.

in preserving the fresh verdure of a lawn, or in furnishing a supply of water to a stable or barn yard.

CANNING RABBITS IN AUSTRALIA.—An instance of the profitable use of what has been, and yet is, a most destructive pest in Australia, is given in the new business of putting the flesh of rabbits in cans for exportation to Europe. Formerly these rabbits existed in such numbers, that not only were the farm crops completely destroyed in some districts, but the grass was devoured, and the sheep pastures rendered useless. Many devices for their destruction were tried without success, until the idea

Fig. 5.—PUMP.

of turning them to account was put into practice. A company was formed which steadily employed a number of hunters to trap the rabbits, for the purpose of dressing their flesh for canning. About 200 tons of the meat have so far been put up, and 5,000 rabbits per day are now canned. The heads are boiled down to glue, and the skins are

Fig. 2.—REAR VIEW OF BOILER, TANK, AND PUMP.

without difficulty. In figure 1 is shown the front view of the boiler, tank, and pump, with the con-

nections for carrying steam from the boiler to the pump and for the water supply. The rear view is shown at figure 2. We have had these engravings very carefully made, showing these connections accurately, so that any person may readily put them together.

preserved for sale to hatters, who use the fur. The farmers are still troubled with the pests, but such wholesale destruction must in time have the effect of reducing their ravages. In parts of Oregon, rabbits have caused very extensive destruction of crops, and a hint may be gathered from the Australian plan, which may lead to measures of relief and turn the pests to profit.

Some Useful Corn Mills.

Corn is so cheap that many do not take the trouble to be saving with it, and no grain is so wastefully

Fig. 1.—"BIG GIANT" CORN MILL.

used. Economy is too rarely considered on American farms. "Lightly come; lightly go," seems to be the principle on which we all are too ready to act, and we throw out our whole grain with a liberality that is both wasteful and costly. Now it is certain, that grain when crushed or ground is worth more for feeding than when whole. It is eaten with less muscular effort, which is in reality no inconsiderable gain, as for every movement of one single muscle there is an expenditure of vital force which requires the consumption of some food to replace it. Ground corn is also more easily digested, and there is less loss of undigested grains, which are carried off with the excrement—a loss which is in some cases equal to a quarter or a half of the quantity fed. To get our grain ground costs 11 per cent of it. For every 10 bushels taken to the mill, we get 9 returned, a cost of one-ninth. For every \$9 worth of corn fed, we pay the miller one dollar. In feeding \$500 worth of grain, then, the loss is equal to \$55. Many farmers pay this amount every year, and besides lose many days time in going to and returning from the mill. Now it is very plain that if a farmer, who has been in the habit of feeding this quantity of grain every year, could procure a mill for the same amount that he pays yearly for his grinding, the mill would be paid for in one year, and ever afterwards the grinding would cost nothing, because it would take no longer to grind at home than to go to the mill. Many farmers, if such a mill be pointed out to them, will avail themselves of its advantages at once. A mill

Fig. 2.—OUTSIDE SHELL OF "BIG GIANT."

that will grind 20 bushels of corn-ears, or 15 bushels of shelled-corn, into meal in an hour, with two horses attached to the sweep, is shown at figure 1. It is the "Big Giant" corn mill, made by Jas. A.

Field, Son & Co., of St. Louis, Mo. The engraving shows the mill set in its frame, ready to be staked to the ground, or to be bolted to a barn floor. It is operated by a sweep, to which the horses are attached, and which embraces the outside shell of the mill, which is shown at figure 2. The inside cone is shown at figure 3. The cutters are arranged upon the upper part of the cone, and the grinding parts at the lower portion. The outside shell is similarly arranged, and by elevating or depressing the latter, by means of set screws, the meal is made coarser or finer. Corn in the ear, or ears with the husk, as stripped from the stalk, may be ground in this mill as easily as shelled corn, the cob being reduced to meal with the corn. The advantage of this to large hog, cattle, or sheep-feeders, is apparent at once. In grinding corn in the shuck, a little extra care in feeding the mill will be necessary. Having seen this mill at work, grinding both shelled corn, and ears yet green from the field, into meal, we can say from personal inspection that it does its work easily and excellently, and is a valuable and effective machine. This mill is also made with gearing, to be operated by water or steam power.

At figure 4 is shown a combined corn-sheller and mill, known as the "Mishawaka Feed Mill," made by the St. Joseph Manufacturing Co., of Mishawaka, Indiana. It shells and grinds at the same time, or does either separately. It can be operated by hand or by power; with power it grinds 15 bushels an hour. The grinding plates are made of hard iron, and are expected to grind 1,000 bushels without being renewed. When worn, they are replaced with little cost and great ease. The mill is simple, durable, and works with light power. It grinds fine enough for feed only. Another useful feed mill is the "IXL" Mill (fig. 5), of the U. S. Wind Engine and Pump Co., of Batavia, Ill. This is

Fig. 3.—INSIDE CONE OF "BIG GIANT."

wholly of iron, and is run by power. The chilled iron grinding plates have grinding surfaces on both sides, and can be reversed. One set is expected to grind 4,000 bushels before they are completely worn out, when they can be replaced. To own one of these serviceable mills, could not fail to be profitable where a large quantity of grain is fed; and where but little is used the convenience of having one's own mill may still be enjoyed if a few neighbors could join in purchasing one. That would save many a tiresome journey to and from a grist mill in disagreeable weather, and over bad roads.

Why We Should Grow Wool and Mutton.

The consumption of wool in the United States is far ahead of its production; a certain market is therefore offered for all we can produce. For several years past, the operation of a tariff has rendered the market for our wool steady and profitable to the growers; and which has helped, if it has not induced, an extension of sheep culture beyond any precedent, and at the same time greatly encouraged the woolen manufacture. The growth of wool and its manufacture into various fabrics, are necessarily closely related industries, and one flourishes or suffers with the other. At the pres-

ent time, our woolen manufactures surpass in excellence those of any other country. The Centennial Exhibition proved this. The finest broadcloth there, was made in the State of Maine, but it is mortifying to us to have to confess that the wool was brought from Silesia, while we are as well able to grow it as are the German farmers. The American

Fig. 4.—THE MISHAWAKA FEED MILL.

cassimeres were not excelled by any from foreign countries; these are made from American fine to medium or merino wool. American flannels are better than similar European fabrics, because they are made from American wool, which is better than any we could import for this purpose. Our blankets are superior to any foreign ones; those made in California and Minnesota surpassed any others that were shown at the Centennial, and the Minnesota blankets are actually exported to Europe for use in railroad sleeping cars. American knit goods of the very best quality are made from our combing wools. A most beautiful fabric, the America "India" shawl, is made from our finest long wool. Our worsted fabrics, delaines, and cashmeres, are made from our home-grown wools; but our alpacaes are made from English combing wool. These last mentioned goods are so excellently made that they are excluding foreign fabrics, and are helping to turn the balance of the foreign trade greatly in our favor. One mill used for these goods 10,000 fleeces weekly. For the first time in our history, our national flag is made of American grown Cotswold wool, as are also the present fashionable bunting goods for ladies dresses. In carpets we excel the long-famed English manufactures. Over 100 factories in Philadelphia, alone, are making carpets, and others are at work in scores of villages and towns. "Ingrain," which has two colors in a line; "three-ply," which has three; "tapestry," which is printed; "Brussels," which is dyed in the yarn; "Wilton," "tapestry-velvet," and "Axminster," which are all velvet; all these are now made in this

Fig. 5.—THE IXL FEED MILL.

country and sold so cheaply that almost every house in the whole land has carpets upon its floors. Lastly, the worsted coatings, with which our men of all degrees and professions are clothed, are

chiefly made from our home-grown medium wools, and were it not for the foolish fashion, which induces many persons to choose cloths of professedly foreign make—but for the most part really home made—we should rarely see any but an American brand upon all our woolen piece goods.

These facts convey an important lesson to the farmer. If he wishes to keep sheep he need not long consider what kind he should select. *Any kind of wool will find a market.* The coarse, short carpet wools of the poor Texan and low grade sheep; the medium wool of the South-Downs, and the half and quarter Merinos; the fine short and long comb-ign, merino wools; the very fine Silesia wools; the long wools of the Lincoln and Cotswood; all these are used and wanted, and none of them come amiss to the manufacturer. But it must be kept in mind that the best sheep is one that produces both wool and good mutton. Mutton is now becoming a staple food in America; 25,000 to 30,000 sheep and lambs are sold every week in the New York city markets. Therefore a sheep that will produce a good carcass of mutton is the kind to be chosen, irrespective of its fleece, by the general farmer. The sheep ranges of the West will produce wool without regard to mutton, because this is most easily transported. No product of the farm is so cheaply carried in proportion to its value, as wool. \$100 worth of wool is carried from Chicago or St. Louis to New York for \$4; while to transport the same value of beef the same distance costs \$20; of pork, \$30, and of corn, \$50.

These figures will help to give one an adequate idea of the staple and permanent character of the wool growing industry, and of its certain profitability. We might strengthen the force of these by a reference to the advantages gained by farmers in the way of improved cultivation, and the increasing fertility of the farm through sheep culture. Of these we cannot now speak, but they are by no means unworthy of regard, nor do they admit of any question as to their certain effectiveness. It is enough now to show that the farmer has a certain market for whatever kind of wool he may grow, if it is good of its kind, and that the mutton is as readily salable as the wool.

Hints and Helps for Farmers.

A "CRAB" FOR SHOCKING CORN.—"H. S. S.," Riverside, Iowa, sends a sketch of a "crab" for supporting corn until the shocks are set up and tied. It is made of a block of wood, 8 inches long, and 2 inches thick, into which one of the legs, four feet long, and an inch and a half thick, shown at figure 1, is fastened securely. The other two legs are loosely inserted, so that when the shock is completed they may be pulled out; when the head of the "crab," with the remaining leg is removed, and the contrivance again set up for another shock. This is found very useful when corn is shocked in wide rows for plowing for wheat. The plan followed is to cut 6 rows, throwing three rows on each side, and then plow that strip and set up the

Fig. 1.—CRAB FOR SHOCKING CORN.

crab for shocking on the plowed ground, then cut 6 more rows on each side, making 18 rows in all,

finish the shocks and go on with the plowing. Then repeat the process.

A NEW BUTTER WORKER.—To work butter with the hands destroys the texture and quality, and to use the common butter ladle is hard work for the hands and arms. A machine that will effectively do this work will be found a great help and convenience in the dairy. We recently procured a butter worker, which is shown at figure 2, made by Henderson & Co., 316 Race Street, Philadelphia, which performs very satisfactorily. It is easy to work, and a child can operate it. The table or tray is hollow, so that the butter-milk runs to the center and there escapes through the perforated spindle into a pail beneath. The ladle rotates, and its action is that of the common hand-ladle in working the butter and freeing it from butter-milk. The gearing is covered, so that no butter can work into it.

Fig. 2.—BUTTER WORKER.

The whole can be taken apart in an instant and cleaned. From 25 to 100 pounds of butter can be worked at one time with the different sizes; the largest size being well adapted for use in country stores where butter, of different qualities and colors, has to be mixed and worked together.

Fig. 3.—HEDGE GUARD.

To PREVENT COWS GOING THROUGH HEDGES.—"H. S. S." fastens a pole 4 feet long to the horns by a strap, as shown at figure 3; to prevent them from pushing down fences, he fastens the T-shaped board (figure 4) on to the horns by the holes seen in the engraving, at the lower end there are a few sharp-pointed nails, which will not prick the nose unless the cow attempts to push against the fence; when the nails give her a sharp reminder that she is trespassing.

Fig. 4.—FENCE GUARD.

A FEED-BOX FOR SHEEP.—"J. H. S.," Logan,

Fig. 5.—BOX FOR FEEDING SHEEP.

Ind., sends a description of a feed-box to accommodate 25 to 35 sheep, an engraving of which is shown at figure 5. The box is made as follows:—The posts, six in number, are 28 inches long, and 2 x 2 1/2 thick. The boards for the bottom and sides are 16 feet long, the former is 14 inches wide, the lower side boards are 10 inches wide, and the upper ones 6 inches; this leaves an open space of 10 inches for the heads of the sheep, which is ample. This sort of box answers well for feeding cut clover, hay, or chopped roots, and prevents the sheep from standing upon and fouling their feed, or getting litter into their wool.

HOW TO USE A GATE FOR SEPARATING STOCK.—When the gates, A and B, are arranged as in figure 6, and both opened together, they will meet at D. If they are then hooked together, small stock only can pass through, as the space is but 18 inches. To move large stock from lot No. 1 to No. 2, the gates are both opened to C, and latched to the post there. This opens lots 1 and 2, but keeps No. 3

closed. To throw all open at once, the gates are swung back to E and F, and latched on to the posts;

Fig. 6.—DIAGRAM OF GATES.

the tops of the posts being cut for this purpose, as shown at figure 7.

A BULL RINGER.—A subscriber sends us a small piece of wood, cut and smoothed to the shape shown at figure 8. This is made to fit the thin part of the ring, tightly, so as to hold its place. The end of the ring, protected by this piece of smooth wood, is passed through the hole made in the bull's nose, much more easily and less painfully than the sharp-edged portion of the ring. When the ring has been inserted, the piece of wood is removed, and the ring fastened in the usual manner.

Fig. 8.

Sloping-Toothed Harrows for Cultivating Growing Crops.

For some years past it has been the practice of many of the better class of farmers to harrow their young wheat, oats, corn, and potatoes, to destroy newly-sprouted weeds, and to loosen the soil. Fall wheat has been harrowed, soon after it had taken a secure hold on the soil, before the winter had set in, and in the spring as soon as the soil had become firm and dry. This has proved to be greatly beneficial to the crops. Young corn, also, has been worked with the harrow until it was a foot high, and with benefit. Still the excellent practice of harrowing young crops is not nearly so general as it should be, and in order that our readers may become better acquainted with it, and the kinds of harrows used for the purpose, we give the accompanying illustrations of two implements designed for this use. These harrows should have, then, teeth slope backwards, at an angle of about 45 degrees; should be light, and their teeth should be fine and sharp. A harrow of this kind is hardly suitable for other uses, and few farmers can afford

Fig. 1.—SLOPING-TOOTHED HARROW.

to have a different harrow for every different work. The implements we here describe are made to meet

the needs of farmers for all kinds of work; for smoothing the ground after plowing, for covering seeds, for gathering weeds and roots from the soil, for stirring summer or fall fallows, and for cultivating growing crops in the manner above mentioned. To meet all these needs, the device of movable teeth has been adopted. When these harrows are drawn one direction, the teeth slope, and they can then be used as cultivators, for covering seed, or harrowing lightly-turned sod without disturbing it. When they are reversed, the teeth are upright, and perform the ordinary work of the common harrow. In principle, both these harrows are similar, but in construction they differ. That

Fig. 2.—BRADLEY HARROW.

of which one-half is shown at figure 1, which is made by the New York Plow Co., of New York, has a wooden frame, and the teeth, of elastic steel, are loosely hung or attached. This device gives the harrow a peculiarly easy motion over growing crops, so that no injury is done to the plants, and the teeth, in passing over the slight depressions in all plowed soil drop down and do their work in those low spots, that would otherwise be passed over without being touched, unless the harrow should run so deeply as to injure the young plants. The illustration shows only one-half the harrow, which is very broad, covering 10 feet in width. A separate tooth is shown, which illustrates its peculiar structure. When the harrow is reversed the teeth are straight and rigid. At figures 2 and 3 are shown the "Bradley Harrow." This is also reversible, and acts in each of the methods we have described, as

Fig. 3.—BRADLEY HARROW REVERSED.

it is drawn in one direction or the other. This has an iron frame, and is so hinged that it bends and conforms to the surface of uneven ground. It is made by the Bradley Manufacturing Company, of Syracuse, N. Y., for whom Messrs. R. H. Allen & Co., of New York, are the sole agents.

The use of these harrows is one of the modern improvements in agriculture. Good farmers estimate the increased yield of grain from harrowing at 5 bushels per acre, and upwards. This is a moderate estimate, but it does not include all the advantages gained. Perhaps the destruction of weeds, which is not only a present benefit, but a permanent improvement to the soil, is of greater value than the increase of crop. A clean field is not only a pleasant thing to see, but the absence of weeds brings money to the pocket in enlarging our crops and in saving labor. A weed killed is so much gained, with the addition that an immense progeny is prevented from following it. Those who have harrowed their grain crops will always continue the practice; those who have never done it, should by all means make the experiment the coming season.

The Trial of Farm Steam Engines at Syracuse, N. Y.

The New York State Agricultural Society, with commendable enterprise, held a competitive trial of portable farm steam engines, at Syracuse, N. Y., on the 12th of November last. The rapidly extending use of steam engines on the farm makes it very desirable that the peculiar merits of the many

good engines now in the market should become widely known, and a public trial is an excellent means to this end. The trial took place at the large foundry room of the Bradley Manufacturing Company. The trial was under the superintendence of a Committee composed of James Geddes, Esq., Vice President of the Society; Prof. Green, of Troy, N. Y., and Henry Waterman, of Hudson, N. Y. The engines subjected to trial were the "Economizer," 10-horse power, made by the Porter Manufacturing Co.; the "Mills," 10-horse power, by the Fish-kill Landing Machine Co.; the "Westinghouse," "Birdsall," "Eclipse," "Mansfield," "Oneida," "Watertown," "Payne & Son's," and a 6-horse power "Economizer," engines. The test applied was the driving of a double-acting pump. Records were made every 15 minutes of the velocity of the engines, the revolutions of the pump pulley, the pressure on the pump, and temperature of the feed water. The water and coal used were accurately weighed. Each test occupied 4 hours. Each of the engines seemed to work well, but the actual result cannot be ascertained with exactness until all the recorded data are figured out and compared. This will require some time, and the report cannot be had until the Committee have concluded their labors. A number of farmers and thrashers were in attendance, and closely watched the proceedings.

Poultry-Keeping—How to Begin.

There is a very general desire to engage in keeping poultry. The business does not require hard work; and is attractive and agreeable. It also promises to be profitable, and profit is the chief inducement to the majority of the novices who desire to attempt it. A few general cautions are needed by those who would undertake this business.

A novice can not, by the mere use of money, take up poultry-keeping and make a success. On the contrary, he will be more than likely to lose all the money he invests, if he supposes that the business consists only in buying some fowls and feed, and in selling eggs and chickens, by simply permitting the hens to produce eggs while he gathers them. Success only comes to the long-experienced poultry man who knows precisely what is to be done to secure this result. It is best to begin with a few fowls, making their keeping a secondary business, until these can be managed with success and profit. Then the number may be increased, and when the business pays sufficiently, then sole attention may be given to it. It is more profitable to purchase fowls than eggs. This is a simple matter of figuring. If a dozen of eggs of choice fowls are procured at a cost of say \$5, a year will elapse before any profit can be gained from the three or four pullets that may probably be hatched from them. If a trio of birds are purchased at a cost of say \$20 now, a number of eggs will be procured before setting time arrives, and then each hen may bring out a brood of eight or ten chicks. After these are raised, more eggs will be laid, and if good care is given, there may be on the whole 20 dozen of eggs, ten pullets and ten cockerels, as the produce of this trio within the same time that it would have taken, from the dozen of eggs first mentioned, to produce three or four pullets. There is an obvious difference in favor of beginning with birds, both as to profit and time.

CHEAPNESS OF PRODUCTION.—In every department of industry the tendency is, to reduce the cost of production, by means of more effective methods and more skillful work. We are even now securing many foreign markets for produce, and for manufactured articles of many kinds, merely because we can produce them cheaply. We are exporting iron, steel, and tools of various kinds, as well as machinery, from locomotives and other heavy engines, to plows and apple-parers. We are sending off cutlery, cotton goods, leather, boots and shoes, clothing, as well as a vast amount of small articles of hardware, "notions," and rubber goods, with agricultural and other raw produce. Generally,

agriculture is beaten in the competition for cheapness of production, and the export trade does not satisfy farmers as to the prices realized. We shall soon mend this in other produce, as we have already done as regards the production of beef, which is exported at a satisfactory profit to the stock men. They have cheapened their product by the use of improved stock, and a similar course of improvement must be pursued in all departments of agriculture, by the use of the best methods and the best stock, seeds, machines, and implements. If by the use of these we lessen the cost of our products, we add to our profits to the same extent; and if we increase the amount of our products at the same time, we can afford to sell cheaper, and yet make more profit than we now do.

A Promising Forage Plant—"Egyptian" or "Pearl" Millet. (*Penicillaria spicata*.)

One's knowledge of a plant sometimes comes in a very roundabout way. Several years ago, at one of the meetings of the American Pomological Society, we found that one of the members from Tennessee, in anticipation of meeting us, had brought a bundle of grasses to be named, among them was one, which, under the not very elegant name of "Horse Millet," was highly esteemed in his neighborhood, but of which he could give us no history. Taking the specimen home, we, upon examination, determined it to be *Penicillaria spicata*. Some botanists do not consider the genus *Penicillaria* as sufficiently distinct from *Pennisetum* but this is not the proper place to discuss this point, and the name *Penicillaria* will answer well enough at present for the grass. Sometime last winter, Mr. A. S. Fuller, the accomplished agricultural editor of the "N. Y. Weekly Sun," received a specimen of the same grass from one of his Southern correspondents, of which he kindly gave us a share, and we intended to cultivate the plants and thus get specimens for an illustration and materials for an article, on what we supposed was an entire novelty. Illness at just the time when spring operations began upset this and other experimental planting, and though we failed to sow the seeds, our friend Fuller did sow them, and obtained a crop of the Millet, concerning which he gave a full account in his department of the "Weekly Sun." But the strangest thing of all is, that the plant is comparatively an old one, and was tested long ago in Connecticut. The knowledge that we were seeking concerning it had already been acquired, and in good part recorded by our former associate, Col. M. C. Weld, who, before he was connected with the *American Agriculturist*, edited that excellent paper, "The Homestead," at Hartford, Conn. Col. W., without knowing that the plant had been under investigation by us, sent an article giving his experience with *Penicillaria*, which he had tested some twenty years ago, and which he had at that time given some account of in "The Homestead." Col. Weld's article was written last spring, but we did not publish it then, as we wished to accompany it with an engraving. This we are now enabled to do through the courtesy of Mr. W. H. Carson, seedsman, No. 125 Chamber St., N. Y., who has secured a limited stock of the seeds. We saw Mr. Fuller's plants, and think that, on account of its short joints, the amount of foliage is greater than that of any forage plant we have seen, not excepting Indian corn. Col. Weld's account closely agrees with that given by Mr. Fuller. Col. W. says:

"I had sent to me the seed of a tall, leafy, luxuriant, rapid-growing grass, that was highly valued in Florida, under the name of 'Egyptian Millet.' We distributed a good deal of seed from our office, and the following results were very uniformly obtained: (I have refreshed my memory from files of 'The Homestead,' especially from the volume for 1857-8.) It would not mature in Connecticut, hence we obtained our seed from the South. It often attained the height of six to eight feet before showing a head. It was very small and unpromising at first, but finally 'tillered' enormously, producing a great many suckers, or rather

stems from one seed. Plants were not uncommon, exhibiting fifteen or twenty stalks, and sometimes as many as twenty-four were thrown up. If cut when three or four feet high, for feeding green, it might be cut several times in one season. The stalks were not large when standing rather thickly, but quite tender and sweet, even when dry. It was exceedingly leafy and succulent when green, and was greedily devoured by cattle. Cut when the heads appeared, and dried as hay, or corn, it made sweet palatable hay, and was much more easily cured than corn-fodder. The largest actual yield reported was over nine and a half tons of dry fodder, per acre. This crop was left until after severe frost, in the vain hope of securing ripened seed, and the amount of fodder had been materially diminished, so that the estimate made then, that, had it been cut before frost, not less than twelve tons would have been harvested, is not improbable. The seed was sometimes obtained clean and sometimes in the chaff, each seed being surrounded by a sort of bristly envelope. The naked seed is somewhat top-shaped, and very small, of about the color of Timothy seed. It was sown in rows or drills, twenty inches to two feet apart, about ten seeds to the foot. It made very slow growth, and seemed unpromising at first, but when the weather became hot, the main stem and tillers shot up very rapidly, until it stood eight to ten feet high, and astonished every one by the immense amount of fodder which a piece of land would produce." In view of the general interest now taken in the Millets, Durra, Guinea grass, and similar fodder crops, we give this, as we have given others, with the best information we can obtain concerning them. Fodder crops of various kinds, in this country, come in competition with Indian Corn, which, though an excellent fodder plant, is not so perfect that our farmers are not warranted in assuming that there can be none better. Should this come into favor, our dealers can readily have the seed grown for them in the Southern States.

A New Double White Violet, "Belle de Chatenay."

It is probable that no one, in looking at the flower of the new double violet, Belle de Chatenay, itself, or its engraved representation, apart from the

DOUBLE WHITE VIOLET, "BELLE DE CHATENAY."

leaves, would recognize it, at first sight, to be that of a violet. The flower of the single violet is characteristically and regularly irregular, while in this double variety all semblance to the usual structure

EGYPTIAN OR "PEARL" MILLET.—(*Penicillaria spicata*.)

of the violet is lost, and we have in place of the normal flower a mass of petals heaped up upon one another to make a "full double." This novelty was introduced by M. L. Paillet, of Paris, the past summer. The attempts of the French nurserymen and florists to give us their catalogues and descriptions in English are sometimes very amusing, and, though M. Paillet succeeds better than some of his countrymen, his description is of the French—Frenchy. He says: "This new Viola is sent out for the first time by me the present season, and is the beautifullest variety known. The flower is very large, about one inch and third in diameter, very double petals, very well set in order like a double camellia flower, pure white and the border of petals embroidered with red purple lilac. This variety is very hardy and will be a precious plant for forcing or market purposes. Variety extra." After all this description, the concluding "variety extra" seems as much an

anti-climax as Mr. Paillet's countryman's comments on a sunrise at sea, when he exclaimed: "Voilà! tres grande! tres magnifique! very good!!" Still, in spite of the producer's enthusi-

asm, we incline to the belief that the plant will warrant it. We have received a specimen from the greenhouse establishment of Henry A. Dreer—an establishment in which, by the way, a worthy son sustains the reputation of our lamented friend, his father, in quietly introducing choice novelties.

Aside from the growers who supply the demand of cities—and it is a large one—for violet flowers, the choice varieties of the European fragrant Violet (*Viola odorata*) are not much grown. Beyond a clump of the common single form in a shady place, to give its sweetest of all flowers in early spring, we see but little attention given to the violet in private gardens. With but little trouble, one may have violets from January until in May they bloom in the open ground. Plants, obtained by setting out runners in spring in rich soil, and giving all the water they need in dry weather, may be set in early autumn in a common cold frame. Allow them to grow until winter comes, then fill up with leaves, put on the sash, and a shutter over that. When flowers are wanted, remove the sash, and take off the leaves, and if the plants were strong, and well furnished with buds, they will begin to bloom in a week or two. Of course, the plants must be treated like others under glass, and have abundant air on mild days, and water as needed. A frame of three sashes, with boards to separate it into three parts, may be uncovered, one sash at a time, at intervals of two or three weeks, and thus keep up a succession of these most charmingly fragrant and universally popular flowers.

THE ONION MAGGOT.—A correspondent of the "Journal of Horticulture" (London) advises the use of hot water, "a little off the boil" to destroy the onion maggot. This he says, if taken in time, is effective, but if the maggots are not attended to before they have eaten their way into the substance of young onions, and are thus beyond reach, neither this nor any other application will be of use. When we last spring mentioned the use of hot water to kill the cabbage worm, and advised its trial, we received a letter of protest from a Canada correspondent. This gentleman, who thought our publication showed a lack of the proper knowledge of the re-

THE THICK-LEAVED ELM.—(See page 22.)

lations of heat to plant life, may now turn his attention to the mother country, where they are so lacking in "common sense" as to use this very old method of killing several kinds of insects.

Small Evergreens for Small Places.

Under the heading here given, we, in November last, called attention to the folly of planting evergreens, which in a few years will become forest trees, in front yards, on small lawns, or other places where the trees, when even half grown, will

be such that the well-developed tree will be too large, do not plant it. There is no greater fallacy than that which leads to the crowding a place with young trees, for immediate effect, with the idea of cutting out the superfluous ones when they become crowded. The idea is a capital one—the trouble is, people will not carry it out. If one who has planted the trees really loves them, and has no place to

from the typical form of the species, that the quick eye of the cultivator will notice it, and set it apart from the rest to test its merits. The Norway Spruce (*Abies excelsa*), being here and abroad one of the most popular of evergreens, has been largely raised from seed, and has, of course, produced a number of seedlings so strikingly unlike the usual form, that they have been continued in cultivation. The cata-

THREE-COLORED TROPAEOLUM.—(See next page.)

be found altogether too large for the situation. An example of this is to be seen in a village through which we frequently pass. The front area, scarcely 10 feet wide, hardly merited the name of a yard. Years ago this space had been ornamented by two little White Pines, and very prettily they looked, no doubt; for it is difficult to find a more graceful little tree than a well-grown White Pine about five or six feet high. But these pines would not stay small, and when we first knew them, had grown as tall as the brick house, against which they stood in a sort of halved state, for their branches could not develop in that direction, and there they stood, two great green fans, quite hiding the house and shutting out light and air from the windows. Recently this, as sooner or later happens to all this ill-advised tree-planting, came to an end, and these trees, set out with so much care, and regarded for a few years with so much interest, are now kindling wood. In these winter days, when all prudent planters are thinking over their plans for next spring—and by planters we include those whose grounds are measured by square yards and rods, as well as those who reckon by acres, the smaller places requiring much more thought than the large ones—it is all important to look beyond the immediate effect, and consider what will be the condition of the trees 10 or 20 years hence—not only with respect to evergreens, but to deciduous trees also. Those not well acquainted with trees, can readily learn from books the size to which the different kinds will reach when full grown, and if the size of the place

which he can transplant his surplus, he will hesitate to put the axe to those of which he has watched the growth for several years, and though his judgment tells him that it will be better for those that remain to cast out one half, in fall he puts off the cutting until spring, and in spring he finds a ready excuse for postponing it until the next fall, and so it goes on, the trees grow up as a thicket, and the beauty of the whole is spoiled. It is easy to find examples of this mistake in all parts of the country. Fortunately for owners of small places, there are trees especially suited to them. If they put off their selection until planting time, and then send off a hurried order, they are likely to be dissatisfied with the results; but if one begins well beforehand, and devotes the time to it that is due to an undertaking, the results of which are to last for a life time, and for many years to come are to be a source of pleasure, or its opposite, to not only himself but his neighbors and the stranger who passes by, there will be no difficulty in finding both deciduous and evergreen trees and shrubs exactly suited to his place, however small or large it may be. In the article in November, we mentioned some of the most desirable small growing evergreens. In looking about our own grounds to see what evergreens, after ten years planting, seem to us the most serviceable for small places, we find two of the Norway Spruces to possess most excellent qualities. In nurseries, where evergreens are raised from the seed by thousands, or millions each year, an occasional seedling will be found, which is so different

THE CONICAL NORWAY SPRUCE.

logues give some 20 named varieties; some of these, like monsters among domestic animals, should have been squelched at birth; but among them are forms, which for certain uses are far superior to the usual one. The variety called *Gregoriana*, or Gregory's Spruce, was a shapely little tree when just out 10 years ago; it is not now so tall as one's head, and a model of sturdy vigor, it being very dense with branches, upon which the leaves are smaller than in the ordinary form, and of a somewhat bluish green. There is nothing dwarfed or stunted in its appearance, but it manages to keep obligingly small, and grow but slowly. Another variety of the Norway is called *Conica*, or the Conical Spruce. This we have not had so long as the other, and can not compare the two for rapidity—or rather slowness—of growth. This, of which we give an engraving, has remarkably upright branches, while those of Gregory's Spruce are spreading; its leaves are longer, and of a lively yellowish green. Messrs. Saml. B. Parsons & Sons, Kissena Nurseries, Flushing, (L. I.) N. Y., from whom ours was procured, state that it is one of the most popular of all the small evergreens. We are not surprised that this should be so, as its exceedingly neat and compact habit, and its pleasing color, joined to a very dwarf stature, all make it a desirable small evergreen for small places. Those who care for oddities will be gratified with the variety of the Norway Spruce known as *pendula*, or Weeping Norway Spruce. Our specimen has been growing some 6 or 7 years, and does not appear to have increased much in

light. It has apparently no aspirations, all its tendencies being earthward; no sooner does a shoot start than with a sort of arboreal depravity, it at once turns downwards, and while in this manner it builds a broad fountain-like mass of branches, its upward growth is very slow. While we can not commend this, if one is to set a very few trees, it may well find a place in a collection of moderate size. This also came from Messrs. Parsons. There is one matter concerning the care of small evergreens, which, though it has been frequently stated, may be repeated here, with emphasis. When there is a heavy fall of snow, these are quite surrounded, and almost, if not quite, covered. The surface of the snow, softened by the sun's heat, and by rains, freezes with every cold spell; and all the while the mass is gradually settling. If the surface snow entangles and freezes around the branches of these trees, while the mass at the same time settles, the result will be to disfigure the tree by a severe distortion of the branches, or what is worse, to tear them off altogether. The only safe method is to remove the snow from around them after every heavy fall, a matter of little trouble, if done at once.

The Thick-leaved Elm, *Ulmus Crassifolia*.

It is now more than twenty-five years since, in exploring that part of Western Texas, that lies between the San Antonio and the Pecos Rivers, that we came across a remarkable Elm. The habit of the tree was more that of an Oak than an Elm, while its dense foliage was made up of leaves so small and thick, and so unlike those of our Northern Elms, that, had we not found the fruit, we might have been in doubt as to the kind of tree. Upon examining the specimens, after our return home, we found that Nuttall, in his continuation of "Michaux's Sylva," had figured and described it (in 1842) as the Opaque-leaved Elm, *Ulmus opaca*, forgetting (as he not infrequently did), that he had already, (in 1834), described the same tree, in his "Flora of Arkansas Territory, as *Ulmus crassifolia*—the Thick-leaved Elm, which is the oldest name, and must be adopted. Nuttall first found the tree upon the upper waters of the Red River, where, in a richer soil than that of Western Texas, it attained a medium size, and afforded a dense and especially acceptable shade. Different persons recognize trees by very different characters. The lumber man, who is among trees, as a general thing, in the winter only, learns to distinguish them by the bark, and this he will do with an accuracy which surprises those who are accustomed to look to other characters. The landscape gardener studies the outline that trees make against the sky, the angle their branches form with the main stem or trunk, and the character of the spray. The botanist is too apt to disregard the points observed by those skilled in woodcraft, and those who study the picturesque effects of trees, as these characters are only learned by long familiarity with the objects, and can not be definitely recorded in descriptions in such a manner that others may make use of them. While the botanist notices any striking peculiarity of the habit, or the bark of the tree, his main dependence in identifying species is upon the leaves and the flowers, and on the fruit in general. While we have often been astonished at the accuracy with which woodmen will tell a tree by its bark, we have in turn as much surprised them by telling the tree from the mere form of the leaf, a character which they do not take into consideration. With this digression, we will say that the leaves of this thick-leaved Elm, are, including their short stalks, only about an inch in length, and half that in breadth, varying somewhat in size in trees in different localities; they are unequal, *i. e.*, with one half larger than the other; very deep green, somewhat shining, and roughish to the touch on the upper surface, and paler below; the margins serrate with blunt teeth. When very young, and but partly developed, the leaves are thickly covered with down. The very small flowers are in clusters of three or four in the axils of the leaves, appearing late in the season, and the small, deeply-notched, and downy fruit ripening in autumn. This

species is mentioned here as one concerning which it is desirable to know more, our interest in it being increased by the fact that a small specimen in our grounds, near New York, much to our surprise, endured the past rather severe winter without injury. Should this not prove to be an accidentally exceptional case, and the tree survive the present winter, there will be good reason to hope that it may be safely added to our collections, as it may, no doubt, to those of England and Southern Europe. By this time, settlements must have extended to the localities of this tree, and we shall be glad to learn from those who live where it grows as to the nature and uses of its timber, and how nearly, in its native localities, it comes to be an evergreen. The engraving is from a herbarium specimen, showing a small twig, with leaves and fruit of the natural size.

Tropæolum as Greenhouse and Window Plants.

Tropæolum is a South American genus of very showy plants, most of which are climbers. The best known member of it is the common garden Nasturtium, or "Sturton," (*Tropæolum majus*), often cultivated for its showy flowers, and for its pungent fruit, to be used for pickling. Other species, especially those with tuberous roots, are only suited for culture under glass, and are so unlike the coarse garden annual in foliage and flower, that one would hardly recognize them at first sight as belonging to the same genus. The "bulbs," or more properly tubers, vary in size from that of a boy's marble up to that of an English walnut, and are offered by the seedsmen with their assortment of autumn bulbs. The leading species are the Three-colored, *Tropæolum tricolorum*, the Blue, *T. azureum*, Jarratt's, *T. Jarrattii*, and perhaps one or two others. The tubers should be potted as early as they can be procured, by September if possible, in light rich soil, and provided with a trellis, or some kind of a frame, usually of wire, or of rattan, to run upon. A very pretty effect is produced by using a very twiggy branch, or the top of a young tree, of some kind, instead of a regular frame. In the greenhouse they may be trained to a wire fixed for the purpose along the rafters, for the freer growing kinds. When the shoots first start from the tubers, they are exceedingly slender, but little larger than a common horse-hair, and before the leaves develop, they make so little show that they may be broken unless care is taken. Several shoots usually start from the tuber, and should be trained out separately to the support, at once, else in a few days they will entwine around one another, and become a tangled mass, from which it is almost impossible to extricate them. When once fairly started, the vines grow rapidly, and may be helped with a little weak liquid manure. They do not begin to flower until the support is well covered with foliage, but if potted early, they will be gay with flowers from March until May. The engraving, given on the preceding page, is of the natural size, from a spray of the Three-colored *Tropæolum*, the flowers of which are scarlet and yellow, tipped with black in unusual and brilliant contrast. They will flower well in a temperature of 50°, and with care will make satisfactory window plants, but they are very sensitive to cold, and any thing like frost will kill them outright. When done flowering, the foliage should be kept growing to mature the tubers, and when this shows signs of fading, water should be withheld, and the tubers allowed to dry off. They may be kept in the pots in the dry earth until time to repot the next season.

A Wonderful Prairie Flower, "The Cockatelle."

BY PETER HENDERSON

The vender of that wonderful novelty, the "Cockatelle Flower," is "Comanche George," as he calls himself. George was one of these terrible fellows, a Texan scout. To dispel all doubts on this point, the garb of the plains is so necessary to

him, that even in the streets of New York, while selling his seeds of the "Cockatelle," his hunting shirt and boots, and that leathern belt, so suggestive of bowie-knives and revolvers, still clothe the stalwart form of "Comanche George." In one of his many wanderings he discovered, on the banks of the Brazos, the "Cockatelle," a flower at once so surprisingly beautiful as to subdue the savage instincts of this man of war, and convert him at once into a peaceful seedsman. He describes this wonderful flower as vieing in colors with any rainbow, the foliage simply grand, and the odor, surpassing that of the Rose and Jessamine combined, is wafted over the plains for leagues. After securing the seeds, he made straight for Washington, and gave the officials of the Botanic Garden the first offer, but through jealousy, or something else, they would not purchase, so George wended his way through Baltimore to Philadelphia, and easily found more appreciative customers. When he reached New York the demand had been so great, that he thought of raising the price from 5 seeds for 25c., to 1 seed for 25c.—so he said—as he wished every man and every woman to be able to feast their eyes (and noses too) on this Texan wonder.

We saw him some time in March, and either because our quarters were scarce that day, or we, too, were jealous of this formidable rival, we failed to secure seeds. But we have seen the products of these seeds in the possession of several of our friends, during the summer. There must have been something wrong in cultivation or climate, for the wonderful flower of the Texas prairies, when transferred to our colder region, is not much of a flower at all, and as for odor—but that is so much a matter of taste (or smell) that it may be as well not to express an opinion on that. In fact, "Comanche George's" flower of rainbow hues, turns out to be nothing more and nothing less than common garden *Okra*, or *Gumbo*. Not a few of the scout's customers are ready to assert that he was no scout at all, never saw Texas; and that he had had a heavy contract with some one for *Okra* seed. When last heard of, he was working his way Eastward, slighting no town of any size worth "doing." He no doubt will turn up in some other section with a fresh supply of "Cockatelle" seeds for the coming spring, and your Eastern readers should be on their guard. It is hardly to be wondered at, that this plausible scamp found so many victims, when we know that not a few "professionals" were unfortunate enough to exhibit to friends plants of the "Cockatelle," the seeds of which they had purchased of "Comanche George." I doubt if there are any fields for humbug so varied as those provided for the amateur horticulturist. Year after year, as regularly as spring comes, the swindlers, now known as the "Blue Rose Men," plant themselves in the most prominent streets of nearly every city of sufficient size in the country, and openly sell what the merest tyro ought to know are impossibilities in fruit and flowers. They don't even go to the trouble to vary the names of their frauds, but the same colored plates of Blue Moss Roses, Blue Dahlias, and Blue Gladiolus, and of strawberries, (growing on trees), as large as turnips, do duty just as they did 10 years ago. A new crop of victims comes up every season, and like gudgeons, swallow these most thinly baited hooks. The other day, on Broadway, at Trinity Church, an old colored man had taken up a position against the fence; at his feet lay coiled a few dozen of spiny briars. I stopped and asked him what they were, and the price, "Dems Rosy bushes—de only Rosy bush dat am fragrum, and dat bloom all de time—jes 25 cents a piece."—"Where did you get them?"—"From de boss, and he get dem from Yourup." The "Rosy Bushes" that "the boss" had imported, were not at all "Rosy," but just the common "Green Brier" or "Cat Brier," *Smilax rotundifolia*, to be found in almost every thicket, or along nearly every neglected fence row in the country, North and South. Some industrious scamp had dug these from the Jersey swamps, and had given to this simple son of Africa to sell as "Rosy bushes." ["Comanche George" has at last come to grief, he has fallen into the hands of an interviewer, and, in an unguarded hour, told who were his patrons, and

his opinions of them. As a result a large number of ladies and gentlemen—people who “think no small beer” of themselves, find their names catalogued in a Sunday paper as victims of this swindle, the amounts out of which they were fleeced, and the rascal’s accounts of their eagerness to be humbugged. Probably these people will recollect what we have often told them, that really valuable plants are never introduced in any such loose way. If a traveling vender or other unknown person offers a seed or plant of any kind as a novelty, be sure that here is a first-rate chance to be humbugged. ED.]

Too Much Shade for Health.

The business of planting shade trees is not perhaps overdone. Ornamental trees, the Maples, Elms, Oaks, Tulip trees, and others, certainly add much to the beauty of our village streets, and we should hardly know how to spare the Lilacs, the Wistarias, the Honeysuckles, the Hawthorns, the Wigelias, and Rhododendrons, and other flowering shrubs, that thrive in the yards, and cluster around our windows. There is no occasion yet, especially in the newer villages, for the tree-planting societies to disband. Country roads still sadly lack ornament and shade. But the tree-planters should certainly have their attention called to the abuse of shade. Such an unusually wet season as this in the East, showers falling almost every week, all through the early summer, intensifies the evils of our over-shaded streets. In many of those old towns which are considered the glory of New England, the trees have been planted so near together, and so close to the house, that sunlight is almost wholly excluded from the dwelling, except at mid-day. Trees are not only on all sides of the house, but they have been planted so thickly, that the branches interlace, and no sunlight falls beneath. Elms that require 60 to 100 feet space, for the full development of their branches, are planted within 20 feet of each other, and Maples, that need nearly as much room, are allowed but 10 or 12 feet. It is gloomy and damp under such trees until mid-day, and the moisture steals into the darkened sleeping-rooms of the house. The carpets and furniture grow moldy, and the people who dwell in these over-shaded houses, grow thin and pale, dyspeptic and consumptive. If New England boasts of her tree-crowned villages, she also mourns over the largest proportion of consumptives in her death-list. These villagers want more sunlight and a dryer atmosphere. The dwelling should have the full benefit of the sun, and a free circulation of the air upon every side of it. The remedy for these overcrowded streets and yards is the axe. Thin out until every tree has room for full development, and a margin of sunlight beyond. It will make handsomer trees, and healthier men. We protest against the abuse of shade.

CONNECTICUT.

Striking Cuttings in Water.

Just now some of the European horticultural journals are discussing the method of striking cuttings in water, as if it were something new. It has been in use for a long while in this country for cuttings of Oleander, Laurel, and other hard-wooded plants, and what is called the “Saucer System” of propagation, is scarcely different. In the “Saucer System” sand is used, but with so much water that it is in a state of very thin mud. The cuttings are placed in this very thickly, and exposed to full sunlight, taking care to keep up the supply of water. The French cultivators have used water for cuttings of very soft-wooded plants, such as Begonias. It is apparently much better for summer work than for winter, and in this, as in the saucer propagation, it is necessary to give the plants full sun-light. They find that bottles of clear glass are better than those of colored glass, and with soft-wooded cuttings, but a very small portion of the lower end is immersed, a precaution necessary to prevent decay. This is a method which may afford the amateur much amusement, and may be useful to those who only wish to make a cutting or two, but the professional florist will hardly care to bother with it.

THE HOUSEHOLD.

Home Topics.

BY FAITH ROCHESTER.

Keeping a Diary.

I find it of some advantage to keep a small diary each year. A journal is a different thing. In the latter you may spread yourself to your heart’s content, but a diary is for business. It should be kept up pretty closely, or be written in every evening, if one would avail himself of all its advantages. Anything will do for a diary, which gives clean space for writing, but a little pocket-book, made for the purpose, with spaces marked for each day in the year, is best. Three years ago I had no ready-made diary when the year began, so I used a small blank book, making the dates as I wrote. But this got us into a “pretty scrape” one pleasant summer day. We called it Saturday, and Mr. R., who had been at home, working on the farm for several weeks, had determined to go back to the city, to work that paid better, (I am ashamed to say it in an *Agricultural Journal*), on that very Saturday. When a neighbor, who seldom left his daily work in the field at this season, came to the door in his clean Sunday clothes, and loitered as though quite at leisure, I said, “I wonder if Mr. J. hasn’t lost his reckoning, and taken this for Sunday.” We thought it must be so, and I related how amused my mother and I had been the year before to see my father dress himself up leisurely one Saturday morning, and sit down in the shady door-way of the same house we then lived in, to sing his Sunday-school song book through, in pleasant memory of the days gone by when he was a S. S. Superintendent, while his usual daily work was waiting quite urgently for his care. A little later I saw my neighbor’s wife, also dressed up for Sunday, and when I asked her about it, she assured me that it was Sunday. The Almanac could not help us out, but I thought my diary would. But that only confirmed my error, because I had been several days behind-hand, and in “writing-up” lately, had

Skipped a Day.

We then talked it over together, but to the other members of the family, one day had been much like another all through the last week. Suddenly we remembered an important event which I had not chronicled at all, and in slipping that in between the other days, we found ourselves in the midst of Sunday, sure enough. I believe Robinson Crusoe never lost track of the time, but I wonder how he could do so. I have had to go to my diary to help our folks to a knowledge of the time more than once, and we have even found by that we were a week behind in the days of the month.

Of course people who send children to school, or who live in the neighborhood of churches, or who have daily association with neighbors, are not likely to lose track of the days of the week or month, but if you think it ridiculous to do so in any case, you should be placed as some readers of this paper are, out of sight of neighbors or a public road, and out of convenient reach of schools and churches.

About Keeping Accounts.

I am inclined to agree with Mrs. Stowe’s Nina as to the futility of keeping accounts. It does not bring the money back after you have spent it, and I am sorry to say that my accounts seldom add up and balance properly, but the daily memoranda in my diary, of money received and spent, has saved me from loss more than once. When I write regularly in a journal, I note down all letters received and sent, and I turn to the diary to see whether it is time for a reasonable expectation of an answer to a business letter. I examine it, too, to learn how long a sack of flour, or a cord of wood, has lasted, in trying to make calculations about family expenses; also to learn how long since the last rainy or sunny day; and if one of the children should get sick, I should wish to trace back, through the various entries in my diary, the different steps of the disease from the prolonged expo-

sure to cold or dampness and the taking cold, or the over-dose of sweet things and resulting stomach ache, to the actual sickness, in order that I might learn how to avoid such trouble in future. The diary is an important ally of the memory.

Beginning Poor.

A young woman asks whether I think it would be safe and prudent for her to marry “John,” when they have less than three hundred dollars to start with. That depends. I decline to give personal advice in this case, though the person asking has my hearty interest and sympathy. The subject will allow of some general remarks.

What position in life do John and Mary aspire to fill? What are their social aims and ambitions? If they must begin as though they were rich, while they are really poor, of course it is not prudent to marry. But there are thousands of happy families where a start was made with less than a hundred dollars. Michelet says that two can live cheaper than one, and a young lawyer once demonstrated to me how he was able to save more from his income since his marriage, while living far more comfortably and happily, than before. But his wife knew how to make the most of everything, and they had sufficient means at first to set up house-keeping in a pleasant and comfortable manner.

Two people who love each other can begin house-keeping with a very small outlay of money, if they are so disposed. They need only to furnish one room, and that with little outlay of money. A cook-stove, a bed, a table, two or three chairs, a few dishes, a lamp, a wash-basin, a tub, and wash-board. These are about all the articles of furniture actually necessary to begin with. Then the

Saving must Begin.

and out of the savings there can soon be purchased other useful household articles, until the establishment is comfortably equipped. I know from experience that carpets and curtains (other than newspapers—and perhaps I should have set down a good newspaper among essential articles), are not among the necessities of life in all circumstances. When they must be had, cheap ones can be found to answer the requirements of utility and beauty. If a young couple, with very small means, begin in this way, and carefully keep out of debt, paying for everything as they buy it, they will find a satisfaction in their purchases which they could never have in the possession of treasures balanced by debt. In order to save anything from the weekly or monthly earnings, there must be careful economy about food and clothing. The most nourishment from the least money must be the aim, and every leak should be stopped, or all outlay for that which brings no real advantage in return.

Beginning Arithmetic.

Some mothers who teach their children at home, find it more difficult to bring them along properly in arithmetic, than in any other branch. This has been the case with me. Geography, with a globe and maps, almost teaches itself. A mother, with a mind at leisure, can manage the arithmetic well enough, I suppose. After the little one has learned to count, it can be taught to put numbers together, either by using a regular Abacus or counting frame, or by using beans, peas, or marks on a slate. The mother can make for it little problems of the simplest character, leading it along gradually through addition, subtraction, multiplication, and division; teaching it to read and write numbers, and preparing it to use a book intelligently when it has learned to read well enough. I have never found a book that suited my needs until a friend sent me lately a “Table Book and Introductory Arithmetic, by Lydia Nash.” This has not a word too much, and it has quite enough. It was compiled by a practical teacher to aid other teachers in drilling their pupils in the simple rules of arithmetic. There is nothing to commit to memory except the simple tables of the four fundamental rules, and no one need require a child to repeat a table, if disposed to teach addition, subtraction, and even multiplication, in a more practical manner. But here the tables are arranged in the best manner, each one followed by a “skipping-around” table. After the tables, we have reading and

writing of numbers, and then simple, graded examples in addition, subtraction, multiplication, and division. There are no rules and no explanations, because the young child, for whom this introductory book is designed, is supposed to depend upon its teacher for oral instruction and explanation. Here is simply something to *do*, in the doing of which the learning comes of itself. This is the modern theory of learning rules: learn to *do* a thing, and then tell us how you did it, or how it can be done. It was the old way to make the child first painfully commit the rule to memory, whose sense it could hardly see, until it afterwards learned how to apply the rule by familiarity with examples. I don't know where the book mentioned above can be obtained, but mothers who see and like the idea, can act upon the same theory by using any book, and omitting rules and explanations (or not requiring that they be committed to memory, but teaching *how*, and explaining *why*, in her own way), or without using any book at all.

The Spoiled Bread.

I thought the fire was going down, and I would not need any more for two hours; so I set the bread-pan in the oven, with the batch of kneaded dough in it, and went up-stairs to work. I was detained longer than I expected, and when I came back to the kitchen, there was a hot fire (kindled up just before I set the pan in the oven, it seems,) and I supposed that my bread was spoiled. I pulled off the upper half of it upon my floured-kneading board, and picked out the remainder, which was half baked, as carefully as I could, and set the rough bits on a baking-pan back into the hot oven. At noon, when the children came hungry from school, they pounced upon these crusty brown-baked bits as something quite rare and good, either alone or in milk, and so not any of that batch of bread was wasted.

Simple Dessert Dishes.

Almost everybody knows "Brown Betty," made with chopped apples and bread crumbs. "How came it to be called "Brown Betty?"—I know how "Joanna" came to be called, so. My great aunt Joanna told mother how to make it, a plain, but good cake, made with some milk, without eggs, and from being called "Aunt Joanna's cake," it came to be "Joanna." I turned aside right here to ask my mother, now sojourning with me, if she remembered how to make

JOANNA CAKE.—Here is the rule: One cup of lopped milk, one cup of sugar, one tablespoonful of butter, half teaspoonful of soda. Flavor with nutmeg, or spice to suit, and use flour to make a rather stiff batter.

This cake would do well to use for a dessert, which may be made of any plain cake, with canned berries. Split open the warm cake, and spread upon each half canned or stewed berries of any kind, laying one layer of cake, when spread, above the other. A plain sponge cake is very nice treated in this way, and makes a rich dessert when served with sweetened cream.

A common cream short-cake, split as for a strawberry short-cake, and dressed with sweetened cream, makes a delicious dessert.

To come back to "Brown Betty." This can be made with almost any kind of fruit. Not long ago, a recipe for Brown Betty, made with pie-plant, appeared in the Basket items of the *American Agriculturist*. The idea is to place alternate layers of crumbed bread (battered or not) and fruit in a pudding dish, and bake or steam the whole. The other day, I used up a quantity of dried peach sauce, which had become rather tiresome, by making a dessert, which gave satisfaction, in the shape of

DRIED PEACH BROWN BETTY.—A layer of peach sauce in the bottom of the pudding-dish, a layer of bread crumbs about an inch thick, sprinkled with sugar; another layer of stewed peaches, and a second layer of bread crumbs and sugar, with enough thin, sweet cream poured over the top to wet the upper layer of crumbs. Bake from half an hour to an hour, according to the heat of the oven. This was eaten with good milk, but sweetened cream would not have spoiled it. A similar plain everyday dessert can be made with dried apple sauce.

A Hanging Basket for a Cool Room.

Mrs. S. J. J., Bergen Co., N. J., wishes to know how to fill her hanging basket with plants suited to a cool room; the house is moderately warmed throughout, and while the room in which she would place the basket is seldom very warm, it never gets cool enough to freeze. It is quite late

BASKET WITH IVY AND HARDY FERNS.

in the season to start baskets of this kind. We might tell our correspondent to send it to a florist's to be filled, but the chances are that most florist's plants, being accustomed to heat, would fail to flourish in a cool room. If Mrs. J. can get from a florist a couple of strong vigorous plants of European Ivy, the rest will not be difficult. Most florists keep Ivy in pots, as there is considerable demand for it during the holidays, and we notice that it is generally on sale at all seasons in the stores of the city florists. But you can, no doubt, get the plants at the florist nearest to you. For the rest, you had better go to the woods. It will not be difficult to find in almost any rocky ravine, or wooded hillside, our largest Evergreen fern, the Evergreen Shield fern, *Aspidium acrostichoides*, a vigorous species, a foot or more high; take up some clumps of this. You will be very likely to find in the same woods the *Mitchella*, or Partridge-berry, also called One-berry, as its fruit is produced by two flowers. This is a capital plant for a cool place. Some sheets of moss, such as is found at the lower part of trees, will be useful. Of course, you can not get these if the ground is frozen, any more than you can soil from the woods, with which (and some sand) to fill the basket. If lucky enough to secure all the materials, set a clump of the fern in the centre, an Ivy opposite each half of the handle, and bits of the Partridge-berry around the edges, so that the vine will hang over the sides of the basket. Probably each Ivy plant will have several stems; train one or more of these around the handle of the basket, and the others to the outside of the basket itself, loosely tying the stems in place with coarse thread. When all are planted, and the surface of the earth leveled, then place on the sheets of moss to quite cover the soil. The moss can be torn or cut into bits to fill spaces between the larger pieces, and all made to look like an entire sheet of green. Press the moss down firmly, to be sure that it will be in close contact with the earth. The engraving shows a basket we filled with just these materials some while ago, and we never had one, even when furnished with expensive exotics, that gave us more satisfaction. These are all shade-loving plants, and do perfectly well in a cool room, where there is but little direct sunlight. Of course, the soil must be watered when it needs it, and the Ivy will be all the healthier if its leaves are

sponged occasionally, to free them from dust, and if possible a good showering should now and then be given to the whole basket.

A Home-made Work-Table and Basket.

In former volumes we have given quite a number of illustrations of articles of furniture to be made from available materials, and we now add one more to the list—a combined work-table and work-basket, from a design sent some time ago. This home-made furniture, if well put together, will be quite as serviceable as that purchased from the cabinet-maker and upholsterer, and may be made at a cost quite insignificant as compared with the other. In the matter of appearance, there is a cosy home-like look about these home-made articles, that is much more in keeping with the surroundings of those in moderate circumstances, than any showily upholstered work of the shops. Those of our readers who find themselves, as many of them do, at a distance from cities, can, by the exercise of a little mechanical tact, provide themselves with articles of use and comfort, which they could not otherwise obtain. A barrel, and a few pieces of lumber, will furnish the materials for the frame-work of this table. The heads of the barrel answer for the base and the cover; these being in two or three pieces, are fastened together by two strips nailed on in the manner of cleats. To the center of one of these fasten an upright standard of a convenient height, as in figure 1; this may be done by putting several strong nails through the base, and it would add greatly to its strength to place two or four short braces between the base and the standard; these are not shown in the engraving.

The strongest and best hoop of the barrel is selected, and four braces, of staves split in halves, or other material, are attached at half way up the standard, one end of each being firmly nailed to the standard, and the other end to the hoop. The frame being finished, as in figure 1, it is to be covered with such material as may be

Fig. 1.—FRAME OF TABLE.

desired, or may be at hand. Glazed cambric of some bright color, covered with Swiss muslin, laid on in plaits, makes a very pretty covering; but the matter of covering is one that admits of a wide variety, and most house-keepers will be inclined to utilize

some material at hand. The covering should be put on with small tacks, and left full enough to allow of its being gathered in at the middle, by means of a cord or band, as in figure 2. The second barrel-head is to be covered on both sides with the material, and may be fastened by a hinge to one of the braces, or left loose. A ruffle or a plaited strip should be put around the cover, and around the top and bottom, to hide the edges of the covering material,

Fig. 2.—TABLE COMPLETE.

and give a finish to the whole. If the covering is not sewed together, but the edges merely lapped over where they meet, the lower part of the table may be used to hold slippers or other articles, which may be put in through the opening thus left. If desired, the table may have casters

attached to the bottom. The upper half may be fitted up to suit the convenience. A single shallow bag of strong material, with an opening to allow the standard to pass through, may be tacked to the hoop, and form one large receptacle, or it may be divided into several compartments. The underside of the cover may be furnished with several pockets to hold articles, and its capacity as a work-stand may be still more enlarged by attaching a row of small pockets around the upper edge of the stand, to hold spools and other materials.

Diphtheria—What to Do.

Believing that much of what is called domestic medicine—frequent and ill-advised dosing—to do much more harm than good, the *American Agriculturist* has, as a general rule, kept its columns free from the many recipes sent as “the best thing in the world,” and “sure cures” for various diseases. While we are opposed to frequent medication for every little ailing, we think that every mother should understand the general laws of health, and sufficient of diseases to know when it is safe for her to apply some simple remedy, and when the case is sufficiently grave to make it necessary to call in medical aid at once. In many cases the success of the physician depends upon his being called at once, while it is too often the case that he is not sent for until all the medical knowledge of the parents and neighbors is exhausted, and the patient still grows worse. There is no disease in which immediate aid is more imperatively demanded than diphtheria, which has been, the past season, and is now, in some neighborhoods, and even whole townships, especially frequent, and often very malignant and fatal. In one family, within a mile or two of the writer's residence, every one of a family of four promising children has been taken away within about a week. Diphtheria is eminently contagious, and every precaution should be taken to prevent it being communicated from one to another. When the disease prevails in a locality, children should be kept as much as possible from contact with others, and as persons in whom it has not manifested itself, are able to communicate the disease, all foudling of children, and “kissing the baby” by callers, should be avoided. Before there is any difficulty of breathing, there is a constant pain at the sides of the throat, and this is accompanied by very fetid breath, and the appearance of whitish spots upon the sides of the throat, (faucet), the back part of the throat, or the roof of the mouth, is an indication sufficiently strong to call for medical examination at once. The remedies employed by physicians are various, but none is so generally used, and none have been found, if used in time, more reliable than the *Chlorate of Potash*. While we do not advise any parent to assume the responsibility of treating so grave a disease as diphtheria, we may suggest how they can essentially aid the physician, and this is of especial importance to those who live at a long distance from the doctor, and where many hours must pass before he can arrive, for in this disease hours are of great importance. Chlorate of Potash, to be had at all drug stores, is a salt in small, white, scale-like crystals, which are not very soluble in water. It may be kept on hand in the form of crystals, or when the disease is prevalent in the neighborhood, it may be well to keep a solution ready for use. It takes about 16 parts of cold water to dissolve one part of the Chlorate, and it is to be used in a saturated solution. To prepare this, it is only necessary to add to water more of the Chlorate than it will dissolve. Half an ounce put into a four-ounce vial of water, will be about twice as much as the water will dissolve. As long as any remains undissolved, the solution is known to be saturated—i. e., the water can take up no more. If the ordinary water is hard, use rain water. Upon the appearance of symptoms which seem to indicate diphtheria, a dose of this may be given every hour, a teaspoonful for a child three years and older, and half a teaspoonful to those under three. It is to be given undiluted, and without any sweetening or other admixture, as its

taste is not very unpleasant. Drink of any kind should not be given for some minutes after a dose, as it is desirable that the solution should remain in contact with the surfaces of the throat and mouth as long as possible. Children old enough to gargle the throat, may take the dose every hour, and every half hour use the same as a gargle. This is only intended to aid the physician's treatment, and is advised only for cases in which some hours must elapse before they can be attended. When the doctor comes, tell him exactly what has been done, and how many doses have been given. Those situated quite beyond the reach of medical aid, can not do better than continue the administration of the solution every hour, day and night, until the spots in the throat begin to disappear, when their frequency may be diminished to two, and later to three hours, giving all the while the most nourishing food. This advice has the sanction of the most eminent medical authorities, but we repeat, it is only to be followed until the doctor comes, and at the first appearance of diphtheria, or what seems to be that, lose no time, but *send for medical aid at once*.

BOYS & GIRLS' COLUMNS.

No. 463.—Puzzle Picture.—Master Green has gone out on a gunning expedition. He would shoot if he could see any game. You and I can see a plenty of game of various kinds, large and small, but there is more than any of you are likely to see at first sight.

The Doctor's Correspondence.

ABOUT THE MICROSCOPE.

Last month most of you no doubt saw that the Publishers had arranged for the manufacture of a Microscope, which is to be called the *American Agriculturist* Microscope, and that it can be had on very easy terms. In offering this Microscope I know that the Boys and Girls were considered quite as much as the older people, as it will prove a great source of amusement and instruction, and is put so very low that it would seem that nearly every one who really wished to have one could get it. Many will no doubt be writing to ask me about it, and I will answer them in advance, that while it may be had for a fraction of a dollar, it is quite as good as those which cost two or three dollars, but of course will not magnify like those large compound microscopes which cost \$25 to \$100 or more. I have no doubt that enough youngsters will have them to make quite a large

YOUNG MICROSCOPISTS' CLUB,

and I shall try to point out, as they come along in season, the different things that you will find it interesting to examine. But this must not be all on one side, for I expect you, on the other hand, to tell me what you find, and what you see that interests you, and that my correspondence, now quite large, will be much magnified by the Microscope. The engravings given last month show

the parts of the Microscope, but there goes with each one a sheet telling

HOW TO USE THE MICROSCOPE.

This shows how to very easily mount the little instru-

Fig. 1.—THE WOOD FROG.

ment on a base or stand, so that you can work more conveniently with it. Then it tells how you can fit up a few little tools that will be very convenient to have, and quite worth the little trouble it will be to make them. Then it points out a number of things that are to be seen, many which you can examine now, and learn to use the Microscope handily. Take it altogether, I think we start off

WITH THE NEW YEAR

with a good prospect of having an interesting time. I expect that a large lot of new comers will join our circle—but there is room for all. The more the merrier, and there is always room for more. So tell your young friends—those who do not already belong to our circle—about the *Agriculturist* and the Microscope, and let us have as large a number as possible in our “Young Microscopists Club.”

W. I. Norton, of New Jersey, whose inquiries concerning the Tree-frog, I answered some months ago, sends a

DRAWING OF A FROG.

He found the frog in the woods, and “had a friend draw a picture” of it. Now just here let me advise W. I. N., and every other boy and girl who reads this, to learn to draw. Had my young friend been taught to draw himself, he would not have been obliged to ask some one else to draw his frog. Every one who can learn to write, can learn to draw. All will not draw equally well, any more than all write well, but every one of you can, with a little trouble, learn to draw sufficiently well to be of great use. This frog of W. I. N.'s friend was not a remarkable one, but it was sufficiently accurate for me to see at once what frog it was taken from. I may have something to say

ABOUT LEARNING TO DRAW

at another time. As to this frog, I could see that it was the Wood Frog (*Rana sylvestris* of naturalists), and my correspondent is right in saying that he never saw it on trees, or near water. It is found in thick woods, preferring oak-woods, from Michigan to South Carolina. It is reddish-brown above, and has a dark-brown patch around the eye, and extending considerably back of it. It is a very active little fellow, and makes long leaps, and you must be very lively if you would catch it, as it has a way of hiding among the leaves that may surprise you. If my friend had watched, he would have found that this frog, like all other frogs and toads, no matter where they may live at other times, go to the water at breeding time, usually in early spring. As the young of all these animals is passed in the

“TADPOLE OR POLLYWOG STATE,”

they all go to the water to deposit their eggs, and then leave them, and the young which hatch from them, to shift for themselves.

CARD-BOARD WORK.

E. M. I know that making toys from card-board is a very pleasing occupation, and that making houses of card-board is even very useful, as one may learn much about architecture in making an exact model of a building. If a young person in trying his hand at one of these only learns how necessary it is to be exact, and to always work from measure, it will be a useful lesson. Some persons are so careless that they can not cut out the stuff for a simple box, and have it all come together right, while the material for such a building as the New York Post-Office was all worked out, a stone at a time, in the quarry in Maine; and when the pieces were brought to New York, they were found to go together exactly, the measure having been given with great accuracy, and the workmen having observed it. One trouble about

CARD-BOARD TOYS

is the room the patterns take up, and space is so scarce with us that we like to use it to the best advantage. However, I will give you one example now, which will show the general plan on which such patterns are made, and if in other months I can find room, I may give others. The pattern, figure 2, is that of a little card-board sleigh.

BY CARD-BOARD,

we mean any stiff paper, or thin paste-board, such as cards are printed on. You may often find boxes in which handkerchiefs, gloves, and other small wares are packed,

Fig. 2.—A CARD-BOARD SLEIGH.

and which are of no use to the shopkeepers when empty, that will furnish good material, and may be had for little or nothing. For nice work, sheets may be bought at the stationers. The first step is to

TRANSFER THE PATTERN TO THE CARD-BOARD,

and it may be useful to know how to do this for other things. You will observe that the pattern has entire lines, and dotted lines; wherever the lines are unbroken, the card-board is to be cut; where the dotted lines occur the card-board is only to be bent, and the directions "up" and "down" show which way. Now to transfer this pattern to the card-board. If you have some very thin note, or other paper, through which, when it is laid upon the pattern, you can see the lines with sufficient distinctness to follow them with a pencil, that will answer. If your paper is too thick, tracing paper would be useful, but as you do not wish to go to any needless expense, you can convert common paper into

A TRACING PAPER

that will answer the purpose. Take the thinnest paper you have, lay it on a clean piece of brown paper—if you use newspaper the ink will come off—and with a clean cloth apply kerosene until it is well oiled. Then with another clean cloth, remove all the kerosene that will come off by wiping. The paper should not have so much kerosene on it as to soil the hands or the page upon which it is laid. Place this paper over the pattern, and the lines will show distinctly. Keeping it in place carefully, or holding it by pins if you can not keep it steady without, take a soft lead pencil and copy the lines—whole lines when whole in the pattern, and dotted if those in the pattern are dotted. Having made this tracing, you wish to transfer it to the card-board. In this case, as the pattern is symmetrical, *i. e.*, both halves alike, all you have to do is to turn over your tracing, placing it *marked side down*, upon your card-board, and then with a lead pencil, or any smooth point, go over the lines upon the wrong side. This pressure on the lines will cause the pencil-mark—or a part of it, to adhere to the card-board, and make a faint outline, but one that may be easily followed, and when you have done this, you can go over the lines on the card-board and make them stronger by the use of the pencil, and thus get an exact copy of the pattern as it appears on the page. This pattern is a regular one, with both halves alike, but if it were one in which the sides were unlike, this would reverse matters and make what should be on the right side, appear on the left and vice versa. So to

TRANSFER AN IRREGULAR PATTERN,

and have it exactly like the original, you must work a little differently. Take the Wood Frog here shown. If you were to follow the directions already given, the frog,

which now looks towards the right, would look towards the left. To avoid this, you make your tracing as before. Then turn the paper over, and go over the lines on the opposite side with a soft pencil. Then place this on your card-board, or whatever the pattern is to be transferred to, with the right side, or that on which the tracing was first made, uppermost. Then go over the lines with a hard pencil or smooth point once more, and you will transfer the lines which were put upon the other side of the tracing, to your card-board or paper, and this figure will be an exact representation of the one copied—as to right and left. Transferring a tracing may be done still more easily and satisfactorily by the use of what is called

TRANSFER OR CARBON PAPER,

such as is used in the manifold letter-writers. This is easily made, though it is smutty work. All that is required is a soft, thin paper, some lamp-black, lard, or castor oil, a plenty of soft rags, and some old newspapers. Mix the lamp-black with castor oil or lard, (in cold weather softened by placing in a warm room for a while), to a thick paste. Lay a sheet of paper upon some old newspapers, and by means of a roll of rag, smear it evenly with the lamp-black paste, rubbing it in well. Then with other soft rags, wipe off all that will come off, and then serve the other side of the paper in the same manner. When properly done, this will not soil the hands, or white paper upon which it is laid, but if you draw a line, or write upon it with a pencil or other hard point, the lamp-black will be transferred at those places to the paper below. This paper is much used for copying letters, and for transferring embroidery and other patterns. But in describing the methods of transferring tracing, we have got far away from our

LITTLE SLEIGH.

The rest is plain enough; the outside lines may be cut with scissors, but the inside lines are cut much more neatly with a pen-knife, the card resting on a flat smooth board. It will be seen that the back of the sleigh and the front or dasher, are intended to lap upon the side pieces; they may be fastened there by a little gum, or by a stitch put through the parts.

SEEING THROUGH A BRICK.

"H. T. W.," Bergen Co., N. J. This is one of the oldest optical tricks, and is quite a thing of the past. The last we heard of it, the deception was put to a good use. At the great Sanitary Fair, held in New York in 1832, to raise funds to supply comforts to wounded soldiers, a lady had found one of these "Penetrating Telescopes," as they were called, and large numbers were willing to pay a dollar into the funds of the Commission, for the chance to see "through a brick." The trick de-

Fig. 3.—A PENETRATING TELESCOPE.

pends upon the well-known laws of the reflection of light, and can be explained by the diagram, fig. 3, which shows one form of the "telescope." One looking in at B sees whatever may be beyond the opposite opening, E, notwithstanding that the brick, A, may apparently be in the way. The trick is performed by

CONCEALED MIRRORS,

or bits of looking-glass, placed at the proper angle. Thus, E being turned toward an object, its image will be reflected from that mirror down to another mirror, F; from F across to H, and thence up to C, where it is seen by the eye placed at B. The instrument is made in other forms that are better calculated to deceive than this, but this shows the principle upon which all are made.

Aunt Sue's Puzzle-Box.

PL.

Het sulo hatt fresfus si grestnor hant eth losu ath icesjore.

ADDITION OF FRACTION.

1. Take two letters from a word signifying array;
2. Take two from another signifying a fruit;
3. Take two from a word, meaning—to disclose;
4. Take two from another, meaning—forefetter;
5. Two from another, meaning—probably;
6. Two from a word, meaning—to make plain;

Add the letters together and you will see what I am trying to do.

TRY AGAIN.

NUMERICAL ENIGMA.

1. I am composed of eighty letters:

My 12, 23, 49,—77, 44, 61,—18, 3, 23, 34, 38,—48, 62, 76,—6, 26, 32, 33—5, 64,—29, 70, 46, is a Proverb of truth.

My 67, 2, 20, 27, 37,—40, 63, 14—43, 19, 49, 11, 16, 32, 1,—78, 1,—65, 8, 71, 66, 17, 22, 70, 4, is a Proverb of caution.

My 28,—1, 45, 33, 42, 13,—24, 73, 32, 20, 21, 69, 75,—10, 54,—45, 50, 2, 9, 25, 29, 48, 14, 39, 8, 40,—15, 63,—18, 35, 36,—33, 66, 56, 7, is a Proverb of honesty.

My 80, 60, 28, 55, 21,—23, 72,—31,—69, 19, 79, 32, 30,—5, 62,—15, 35, 51,—1, 59, 49,—38, 53,—6, 44, 78, 23, 33, 52,—41, 2, is a Proverb of education.

My 59,—41, 8, 63, 58,—21, 73, 47, 57,—10, 27,—74, 20, 34, 19, 68, 22,—37, 70,—12, 13,—69, 35, 78, 42, 16, 29,—43, 38, 28, 40,—41, 3, 26, 31, 46,—17, 25, 69, 41, 36, 54, is a Proverb of reputation.

My whole is a Proverb of Solomon.

2. I am composed of 47 letters:

My 38, 30, 22, 23, 22, is the name of a goddess.

My 20, 8, 44, 34, is a river in Africa.

My 3, 14, 37, is a kind of fish.

My 32, 11, 2, 18, 7, we have in spring.

My 40, 33, 36, 47, is an article of apparel.

My 4, 23, 1, is a vehicle.

My 5, 28, 10, is a kind of dwelling.

My 45, 9, 18, 12, 34, 42, is a city in New York.

My 13, 19, 23, is what some people drink.

My 39, 46, 26, is a woman's name.

My 24, 30, 41, 5, 21, 31, may generally be seen on the dinner-table.

My 43, 44, 16, 6, 27, 3, 21, may often be seen on a dress.

My 15, 2, 25, 8, 29, is a strait.

My 17, 2, 20, is much used in summer.

My whole embodies the names of a god and goddess, with some information about them.

IDA S. TERRY.

3. I am composed of 10 letters:

My 1, 8, is to move forward.

My 10, 5, is a boy's nickname.

My 6, 3, 4, is to do evil.

My 3, 2, 8, 9, is very strong.

My 5, 8, 7, is something very small.

My whole is a very useful implement on a farm.

E. S. D.

4. I am composed of 12 letters:

My 3, 8, 10, is an animal.

My 11, 2, 3, 11, 1, 12, is a kind of corn.

My 5, 4, 9, 1, 2, is a musical instrument.

My 7, 1, 4, 1, 7, 7, 1, 6, is a city in North America.

My whole is a river in North America.

6. One has a lop-car like a rabbit.

JOHN W. WHEATLEY.

SQUARE PUZZLE.

Take seven christian names of seven letters each, and place them one below the other, so that another name of seven letters shall be revealed in the diagonal letters, beginning at the upper left-hand corner and finishing at the right lower.

DIAMOND PUZZLE.

1. A vowel. 2. A heavenly body, which forms the center of a system of orbs. 3. The American Ostrich. 4. A name. 5. The act of being contemptuous. 6. To prosecute. 7. One-fourth of five.

The center letters, perpendicular and horizontal, form a name with which we are all familiar. K. P. N.

RHOMBOD PUZZLE.

Across.

1. A bird. 2. An animal. 3. Incurring punishment. 4. A twist of thread. 5. A native of India.

Downwards.

1. A consonant. 2. A preposition. 3. A covering. 4. Animals. 5. Liquors. 6. A value. 7. To cut short. 8. None. 9. One of many. NUTMEG.

ANSWERS TO PUZZLES IN THE NOVEMBER NUMBER.

METAGRAM.—Stream—from which may be made the words Sam, east, steam, team, mare, ram, tame, rat, tea, arm, sea, tar, mast, ease, mate, star, (Mars), rest, stare.

TRANSPOSED AVIARY.—1. Goldfinch. 2. Humming-bird. 3. King-fisher. 4. Nightingale. 5. Starling. 6. Pigeon. 7. Falcon. 8. Swallow. 9. Pheasant. 10. Partridge.

NUMERICAL ENIGMA.—Bestirring, man, while yet the day is clear.

NINE CONCEALED FRUITS.—Orange, lemon, pear, peach, currant, plum, prune, grape, apple.

Send communications intended for Aunt Sue, to Box 111, P. O., Brooklyn, N. Y., and not to 245 Broadway.

Aunt Sue's Chats.

MRS. S. S. D.—A very pretty edging, for the purposes you name, may be made with braid and crochet-work. Get Sutor's feather-edged braid, No. 3 (see fig. 1), (it is sold by the piece of 12 yds., for six cents; proportionally cheaper in larger quantities), Clark's cotton No. 40, and a fine steel crochet-needle. Fasten the cotton into the fourth or fifth loop from the end of the braid (to allow for raveling). Make a chain of six stitches, then put your needle into the next loop but one, with short-crochet. Now make a chain of five stitches, and put your needle through the next loop but one with short-

Fig. 1.—FEATHER-EDGED BRAID.

crochet. Again a chain of five stitches, and your needle through the next loop but one. Now take up the next eight loops of the braid with short-crochet, and you will have reached the point illustrated in the last scallop of figure 2. The eight loops just finished fill up the inside of the lower edge of the scallop. Now make a chain of two stitches and join it in the third stitch (just drawing the thread through) of the lowest chain of five; then a chain of two stitches, and turn back into the second loop (from the eight short-crochet stitches) of the braid; then a chain of two, and back into the third stitch of the next chain of five; a chain of two, and into the next loop but one; then you make a chain of three, and draw your thread through the center of the chain of six; a chain of three, and into the next loop but one. This

Fig. 2.—WIDE EDGING.

completes the scallop. For the commencement of the next scallop (and to join the two) put your crochet-needle through the loop next to the one which is directly underneath the stitch you have on your hook, on the lower side of the braid; turn it over on the wrong side, and double the braid so as to bring the loops (between the two scallops) opposite to each other, then draw your thread through two loops at a time (the two loops which are opposite to each other), leaving the stitches all on the needle, until you come to the loop above the eight short-crochet stitches inside the lower part of the scallop;

Fig. 3.—NARROW EDGING.

then draw your thread through the first stitch, on the hook, then through two and through two until you come to the end of your stitches. Now turn it over on the right side, flatten it out, and just at the top of the joining there will be one little loop of the braid standing up by itself; through that you draw your thread and com-

plete another scallop, beginning with the chain of six as before described. The illustrations may enable you to see through what my explanation has left obscure. To make a narrower edging, like figure 3, leave out the second "chain of five stitches"; to make wider edging, increase your chains of five, and take up more loops on the inside of the scallops.

JESSIE W.—You will find a description of toilet-set (pincushion, mats, catch-alls, card-case, hair-pin box, etc.) in the June No., 1876, of the *American Agriculturist*, p. 226.

"W."—The symbolic meaning of precious stones in Germany is:

Amethyst.....	Control of the passions.
Aqua marine.....	Misfortune.
Agate.....	Long life and health.
Bloodstone.....	Courage and discretion.
Chrysolite.....	Preservation from folly.
Diamond.....	Innocence.
Emerald.....	Happiness.
Garnet.....	Fidelity to promises.
Opal.....	Hope.
Ruby.....	Oblivion and grief.
Sapphire.....	Repentance.
Sardonyx.....	Conjugal fidelity.
Topaz.....	Friendship.
Turquoise.....	Success.

For the initials "C. L. P.," I can think of nothing better than *coral*, *lapis lazuli*, and *pearl*. It would certainly be a peculiar combination, and "C. L. P." would be very sure that you had the ring made especially for her.

CHARLIE.—Yes; "alligator skins" are tanned, and used for boots and shoes. Nearly 20,000 are tanned yearly (the sides and underneath parts, not the backs). They are stripped off, packed in brine, and sent North, from Louisiana and Florida, to be tanned. It takes from six to eight months to prepare them for use. The alligators are sometimes 12, and rarely 15 feet long.

"S. M. F."—An old newspaper, slightly dampened, is the very best thing with which to clean a looking-glass.

"A. M. M.," asks me how to make a "shell-frame." The question is somewhat indefinite, but I suppose she means "how to make a frame of shells." I never had much of a fancy for shell-work, it is so perishable; the shells are always falling off, and getting lost, leaving an ugly gap somewhere. But if I had plenty of pretty shells, and wanted a frame of the kind, I should procure a suitable wooden frame for the purpose; then I should cut a paper the exact size of the frame. On the paper, I should arrange the shells in some tasteful uniform or multiform manner, until it was completely covered. Then I should smear the frame with a strong, stiff glue (a small portion at a time), and transfer the shells from the paper to the frame, one at a time, retaining the position (originally arranged on the paper) as nearly as possible. [Sometimes the frame is covered with a thin layer of putty, and the shells imbedded in that.—ED.]

Thanks for letters, puzzles, etc., to M. Marchand, Charlie F. B., Ida C. C., Augustus J. W., S. G. S., J. R. H., Mary Gold, Sallie, and others, whose favors I hope to answer at some future time.

Where Does the Wheat Go?

Every boy or girl who lives in the grain growing States takes an interest in the wheat crop. They see wheat every where, they hear wheat talked of, and they know that the wheat is sold that sugar, shoes, and many other things may be bought with the money. The girls and the quite young boys, if they take no part in the work of raising the crop, can admire it, and they early learn to know that the fields so bright and green in fall and spring are wheat fields. Later, what a beautiful sight it is, when the tall grain is moved by the summer breezes, and it rolls in waves like those of the sea! Later still, the green gives way to the rich tint that shows that the grain is ripe, and soon you hear the click of the reapers, and then come the hurry and the buzz of the thrashing time. All these make the wheat crop a most interesting one, even to the young people who can not work at it. But the older boys are sure to have a hand in the crop at some time, if it is only to drive the horses or otherwise help at the thrashing machine. It must be a dull kind of boy who can keep quiet when thrashing is going on, where all is so active and every one is doing something with all his might. The horses are pulling, the drivers shouting—or if an engine is used, the steam puffing—the machine going with a tremendous racket; even the air seems full of chaff, and straw, and shonts, and sounds. Where so much is going on we say—a boy that is any sort of a boy—is sure to catch the spirit, and he does something. When at the thrashing machine, do you ever think what all this bustle and rush is for—what does this crowd of horses or steam, of cogs and cranks, of men and boys, all this noise and dust—what does it all accomplish? Go to the delivery spout of the machine, and what do you see? A little stream of small yellowish or brownish grains—the wheat running into a bag. But this hurry-skurry of thrashing is only the end of a long line of operations. Months ago there were strong

horses at work with plows, harrows, drills, and rollers. There was the farmer's anxiety about snow, and freezing, and thawing, he was watching for insects and smut. Then came reapers and binders, and hawking and stacking—all this work running through months, and all that this little stream of wheat might quietly run from the side of this very noisy machine. Is it worth all this trouble and all this labor to get just those grains. What are they—what are they good for that they should be produced at such a cost—that machines and animals, that men with their hands and with their thoughts, should all combine to produce these little grains of wheat. If we were by, we might play the conjurer of the old fairy tale, and say: "If you would see that stream of wheat as it really is, take this magic glass and look through it. This is a wonderful glass; it is called 'The Imagination.' Every boy, and every girl has one, but they do not always know it, and some who do know it and try to use the glass, look through the wrong end and see things as they are not. But look now at the wheat and what do you see in the stream?"—"Steamships and watches. A Senator making a speech and a cook making a pie; fine laces and silks, and gunny bags and ropes; a thief going to prison, a preacher going to his pulpit; books—books, and more books; newspapers and pictures; a microscope and a locomotive, washing machines and sewing machines, such a lot; looms, reapers and—there, take your glass, I am tired—there is too much—there is everything."—"Wheat is bread. That 'bread is the staff of life,' is a saying so true that many persons think it is from the Scriptures. Wheat is the main support of life in all civilized nations, and life shows itself in innumerable forms, a few of which we have supposed our youngster saw by the aid of 'The Imagination.' It is no improper use of the imagination to see in the wheat those things which but for the wheat could hardly be possible. In writing thus we would show the farmer's boy that in raising wheat, he is doing something more than getting so much a bushel for it. He is helping on the world's progress; he is furnishing food to the muscles and the brains of the world, and these muscles and brains in turn help him with better plows and thrashers, and send him books and papers to nourish his brain in return. We would show him that while we are all engaged in doing the world's work, the farmer's part is one of the most important and honorable. You can see that this little stream of wheat, insignificant though it looks, is really important. Each grain is full of power, quiet now, but capable of being awakened. In a stream of gunpowder, each grain can exert an immense power, but that is exercised suddenly and dangerously—while the power in the grain of wheat, is exerted gradually, it becomes bread, and bread feeds the muscles and the brains, and its final power is shown in the work these do, which (though sometimes turned to evil) is generally for the good of mankind. These precious grains are really worth all the trouble, all the hard work, and all the anxious thought through the months between seed time and harvest, until amid all the hurly burly of thrashing, they can run in a stream, quiet, but

STEAM ELEVATOR FOR LOADING SHIPS.

how full of concealed power, from the outlet of the thrasher. Where does the wheat go then? "To the mill," you will say. That which the farmer sends himself to the mill—even that used in his own neighborhood, is but a small part of his whole crop. The rest finally gets to the mill, but what a long journey much of it takes. Between the field on your farm and the thrashing machine at your barn, to the mill, is often thousands

of miles. If you were to trace the journey of a bushel of wheat from your farm to the table where it is eaten as bread, it might take you a long distance, and through many strange scenes. You see the sacks of wheat loaded upon the wagon, you know that they go to the nearest railroad station, or it may be to a shipping point on the river or lake, and then your knowledge of it ends. The East has been these many years sending its people to the West, and now the West sends its grain Eastward. It comes by railroad and canal, and at last reaches the coast. It may be made into flour in New York, Philadelphia, or Baltimore, and make its last appearance on the table of a Fifth Avenue palace or a Five Points hovl. But most of it must keep moving, and go on and on across the wide Atlantic before it finds a mill. The steamers sailing from New York to Europe on Saturday, a few weeks ago, took 263,000 bushels of wheat on that day, and every Wednesday and Saturday similarly large quantities are taken away. Some of you wheat raising boys can calculate how many farms like yours it will take to make up the quantity taken by the steamers on that one day. These steamers often have to unload and take in their return cargo in three or four days, and you may be sure it is busy times with them; the work goes on day and night, and while the imported cargo is going out at one end, the export cargo goes in at the other end of the enormous ship. As you well know, it would be very slow work to shovel up all this grain and carry it on board in baskets, so steam is called into use. The wheat—possibly some of that from your own farm, is brought to the side of the ship in canal boats or barges, and from there it is loaded upon the steamship by means of a "Steam Elevator." The engraving shows how one of these looks by the side of a ship, and its outside appearance; it is not rare to see two or three of these at work at one steamer. These elevators have an endless band, to which pockets or buckets are attached, and this being moved by a steam engine, a continuous row of pockets, full of wheat, is going up to the highest point of the elevator; there they pass over a wheel, the wheat falls out and a row of empty pockets is going down on the other side. The result is a large stream of wheat, running from the elevator, which may be directed by means of spouts to any part of the hold of the ship. At last the great steamer gets her load, not only of wheat, but of flour, pork, beef, and many other of the products of our farms, even to the eggs from your barn-yard, and starts at the very hour—with all the promptness of a ferry-boat—on her way across the ocean. These grains of wheat, how they must be tossed and rubbed, and as the steamer goes plunging on and on, every day and hour carrying it farther and farther from the farm where it grew. At length after its long journey by land and sea it gets—the destination of all wheat—to mill. Where does it at last appear as bread? Who can tell? It may be in the scantily furnished home of some workman at Manchester, or in the castle of some nobleman; it may be at the table of a London clerk's boarding-house, or possibly at that of the Prince of Wales at Sandingham, or of the Queen herself at Windsor. All, workman, nobleman, clerk, Prince, or Queen, must have bread—they are all equal in this—bread is a universal want, and our fertile farms, our industrious farmers, and you, wide awake industrious boy, as you help whether by working in the field or at the thrashing machine, all are contributing to answer the world's great cry for bread.

A Distinguished Visitor from Africa, P. Pongo, Esq.

Probably there has not been in many years an arrival in Europe which caused so much excitement among a certain class as that of the subject of our sketch. The Emperors, Princes, Mayors, and other high dignitaries, made a great fuss, a while ago, over the visit of the Shah of Persia. More recently our own Ex-President General Grant has received, not only from the officials, but what is much better, from the people in general, a magnificent welcome. But it is doubtful if the arrival of the Eastern

the party, who took the animal to Europe, and finally sold it to the managers of the Aquarium at Berlin for \$5,000. It then was no longer a mere animal—a young gorilla, but Mr. Pongo, and under that name his fame extended all over the civilized world. Never was a young Royal Highness more carefully watched than was Pongo. What he did when awake, how he slept, what he had for breakfast, what for dinner, and what he did between meals were closely studied, faithfully recorded, and the intelligence sent all over the world. Berlin had Pongo, and London was Pongo-less, and this would never do; London endured this for two years, and at last sent to Berlin

and had the young Gorilla brought over. Once in London poor Pongo had a hard time of it, he was written up in all the daily papers, and pictured in all the illustrated weeklies; the scientific men came and they measured his bones and counted his ribs, they talked about his "facial angle," and his "occipital ridge." At last Pongo went back to Berlin and—soon died. Whether London fog, or London science, was too much for Pongo, we probably shall never know. He went back to Berlin and died very suddenly, and all that is left of him is his many portraits, one of the best of which, from a London journal called "Our Little Folks" is given here. When this picture was taken, Pongo was supposed to be about three-and-a-half years old, he was between three-and-a-half and four feet high, and weighed forty-three pounds. Though covered with hair, and going on all fours, Pongo was looked upon as being more like a human being than any ape or other animal ever before known, but it only needs a look at his portrait, where he naturally uses his foot as a hand, to see that he is very far from a human being, even the lowest and most degraded of which we have any knowledge. He showed considerable intelligence, but not more than is exhibited by some dogs; and though he had been taught to sit at the table and eat very much what his keeper ate, and even to take his food sometimes with a spoon, he showed his natural tastes by preferring to sit upon the floor or to swing upon a trapeze, which was provided for him. Poor Pongo

PORTRAIT OF PONGO—THE YOUNG GORILLA.

Monarch, or a Western Ex-President, was ever viewed with so much interest, as has the arrival of an individual from Africa, with no title at all, by a few men of science. Monarchs and ex-Presidents were after all but men, while one individual from Africa was much less than a man, and that very fact made him all the more interesting. Travelers in Africa had long ago given accounts of wonderful creatures who were found there, creatures as large as the largest man, and with strength to do wonderful things, such as crushing a gun-barrel in their teeth, and carrying off the natives in their arms. Later, skulls and skeletons, and stuffed skins of this creature—known as the Gorilla, were sent first to this country, and later to Europe, and these only increased the desire to know more about the animal. It was stated by travelers that the ferocity of these creatures was unbounded, and that even when taken quite young it was impossible to tame them. Several young gorillas were shipped to Europe, but they somehow died, or otherwise disappeared before they reached port, and this was given as additional evidence that the animals could not be tamed. An African captured a very young Gorilla, and sold it to a Portuguese gentleman living in Africa, for a small sum. A Prussian Exploring Expedition happening to stop at the village where the Portuguese lived, that gentleman gladly gave the young Gorilla to one of the members of

died before he could teach us much about his people—that is, the full-grown gorillas of the African forests.

According to the accounts of travelers, they grow to be five-and-a-half feet, and some say over six feet high. The skeleton is in many respects more like the human skeleton than that of any other animal; the bones of its limbs are wonderfully large and strong, and while its head is large, that part of the skull which holds the brain is very small. Indeed the brain of the largest gorilla is not half the size of that of the lowest savages yet known. The gorillas are said to go in troops of four females and one male; the two sexes being somewhat different in color, the hair on the males being grayish, and that of the females, blackish. The gorilla is found principally in the western part of Africa, in the forests north and south of the equator. The males are exceedingly savage, and do not hesitate to attack a man if he comes in the way. They are said to come towards their enemy, beating their breasts and roaring terribly, and to be most dangerous. Yet as human-like as gorillas seem in some respects, several of the African tribes eat its flesh, while other tribes will not eat the flesh of this or the chimpanzee or other apes, because they are so much like man. Pongo has proved so interesting, that no doubt other gorillas will be taken from their homes and taught the ways of civilized life, and we hope may not share Pongo's fate.

Pure Gum RUBBER BOOTS!

Will Outwear Common Rubber Boots.

Made by the "CANDEE RUBBER CO." with a view to great durability, and differ from ordinary Rubber Boots in being entirely free from adulterative mixtures. Made of Pure Para Gum, compounded only with the ingredients necessary to "vulcanize" the goods to insure uniform pliability in any temperature.
Durability being the point aimed at, the Boots are made as pure as possible, without regard to a highly finished surface, and the sulphurous appearance of the "Candee" Boot is evidence of its purity.
Buyers should beware of imitations, as "dull finish" Boots of cheap quality are on the market and are sold to the unwary for "Pure Boots." All Para Boots are branded thus:

No orders received at Factory. Ask your dealer for the "Candee" Boot.

H.W. JOHNS' PATENT ASBESTOS PAINTS

These Paints are in every respect strictly first class, and second to no others in the market in purity, richness, and permanency of color, beauty of finish, and durability. They are prepared ready for the brush, in twelve newest shades, and standard colors, and are suitable for the tasteful decoration of all classes of buildings, inside and out, and for all purposes where a perfect protective coating is required.
They contain no water, alkali, or other useless or deleterious ingredients, such as are used in nearly all the liquid or so-called chemical paints, and are guaranteed to be the most durable paints in the world for outside work.

Owing to the wonderful covering properties of these Paints, the farmer, merchant, and manufacturer can, by their use, preserve and beautify their buildings, fences, or other wood and iron work, at from one-half to two-thirds of the usual cost of other ready mixed paints, or white lead and linseed oil. These Paints are sold by standard U. S. gallon measure, and our packages contain from eight to TWELVE PER CENT MORE PAINT than those usually sold.
ASBESTOS ROOF PAINT for tin and shingle roofs, iron-work, agricultural implements, fences, out-buildings, etc. We guarantee this to be a better article than has ever before been offered to the public for similar purposes.

All for sale or to lease by **JOHN B. SMITH, East Hartford, Conn.**

Soluble
Pacific Guano.

The Superior excellence of this Guano has been so successfully demonstrated during the past ten years in the Middle and Southern States, on cotton, corn, tobacco, sugar-cane, and garden vegetables—the Company's sales having exceeded the enormous aggregate of 35,000 tons in a single season—that it is now offered for sale with entire confidence as to its merits. No fertilizer ever introduced in this country, has undergone severer tests, or come out of them with its character as a first-class, reliable fertilizer more thoroughly established. In consequence of the satisfactory results of these very complete tests, this Guano has acquired a reputation equal to that formerly enjoyed by Peruvian Guano. It is rich in **Bone Phosphate of Lime**, finely ground (a large proportion of which is immediately soluble), **Ammonia**, and **Potash**, besides other ingredients valuable as plant-food, manufactured at the Company's works, Woods Hole, Mass., and Charleston, S. C., under the supervision of competent chemists.

PACIFIC GUANO CO., BOSTON.

CHEAPEST FERTILIZER
BECAUSE THE BEST.

THE SUN.

1878. NEW YORK. 1878.

As the time approaches for the renewal of subscriptions,
THE SUN would remind its friends and well wishers every-
 where, that it is again a candidate for their consideration
 and support. Upon its record for the past ten years it relies
 for a continuance of the hearty sympathy and generous co-
 operation which have hitherto been extended to it from
 every quarter of the Union.

The **Daily Sun** is a four-page sheet of 28 columns; price
 by mail, post paid, 55 cents a month, or \$6.50 per year.
 The **Sunday** edition of **THE SUN** is an eight-page sheet
 of 56 columns. While giving the news of the day, it also
 contains a large amount of literary and miscellaneous matter
 specially prepared for it. **THE SUNDAY SUN** has met
 with great success. Post-paid \$1.20 a year.

The Weekly Sun.

Who does not know **THE WEEKLY SUN**? It circulates
 throughout the United States, the Canadas, and beyond.
 Ninety thousand families greet its welcome pages weekly,
 and regard it in the light of guide, counselor, and friend.
 Its news, editorial, agricultural, and literary departments
 make it essentially a journal for the family and the fireside.
 Terms: **One Dollar** a year, post-paid. This price, quality
 considered, makes it the cheapest newspaper published.
 For clubs of ten, with \$10 cash, we will send an extra copy
 free. Address

HENRY HOE, Sole Agent. JOSEPH GILLOT & SONS.

National Repository

Publishers' Special Offer.

A SUPERB ENGRAVING

FOR

Every Subscriber.

In this magazine the Christian home is furnished
 with the higher class of literature, free from all
 objectionable matter and sentiment. It is popular
 where it is known, and, during its first year, has
 gained an encouraging circulation.

To every cash subscriber at three dollars, with
 twenty cents additional, to cover postage on the
 magazine, we will send the original and elegant
 steel engraving, entitled

"Evening Contemplation,"

Designed by **S. J. GUY, N. A.**, and engraved by the
 eminent artist, **A. H. RITCHIE, N. A.**—a large pic-
 ture, 21x29 1/2 inches, being produced in the best
 style of the engraver's art.

Please hand your subscription to any Methodist
 pastor, or forward it yourself, with the subscrip-
 tion price and postage (\$3.20), to either address
 named below. The January number will be mailed
 on receipt of the subscription, and the engraving
 will be sent as soon as practicable. If sent by mail
 direct to the subscriber, ten cents must be remitted
 to cover postage on the same. If sent in a package
 with others to the pastor, it will be at our expense.

Please consider this opportunity of se-
 curing the **NATIONAL REPOSITORY**,
 which has taken rank with the standard
 monthlies, and a rich and rare engrav-
 ing, for the ordinary price of the maga-
 zine.

Address orders to **NELSON & PHILLIPS, New**
York; **J. P. MAGEE, Boston**; **JOSEPH HORNER,**
Pittsburg; **H. H. OTIS, Buffalo**; **J. B. HILL, San**
Francisco; or **HITCHCOCK & WALDEN, Cincinnati,**
Chicago, or St. Louis.

HITCHCOCK & WALDEN, } Publishers.
NELSON & PHILLIPS,

Golden Hours.

A HELP FOR THE HOME.

CHRISTIAN PARENTS.—You have a care for
 the associations of your children. Have you con-
 sidered the influence of those silent companions
 they have through what they read? They com-
 mune with the author as really as though he dwelt
 in your home. If he interests them by what he
 says, they can not read without being affected in
 mind and heart.

The **GOLDEN HOURS** is a beautiful and pure
 magazine, designed to furnish reading for the
 BOYS and GIRLS that will give them happy hours
 every month, and make them wiser and better. It
 costs only **\$1.60 per Year, post-paid.**

Please order through your pastor, or send direct
 to either **NELSON & PHILLIPS, New York**; **J. P.**
MAGEE, Boston; **JOSEPH HORNER, Pittsburg**; **H.**
H. OTIS, Buffalo; **J. B. HILL, San Francisco**; or
HITCHCOCK & WALDEN, Cincinnati, Chicago, or
St. Louis.

Every Premium article is new and of the very best manufacture. No charge is made for packing or boxing any article in our Premium List. The Premiums, Nos. 15, 18, 29 to 33, 37 to 41, 49, 51, 54, 55, 59 to 62, 65, 75, 76, 86 to 102, inclusive, will each be delivered FREE of all charges, by mail or express (at the Post-office or express office nearest the recipient) to any place in the United States or Territories.—The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance desired. Illustrated and Descriptive List sent free to applicants.

AMERICAN AGRICULTURIST.
ORANGE JUDD COMPANY, Publishers, 245 Broadway, N. Y.
ANNUAL SUBSCRIPTION Terms (always in advance):
\$1.60 each for single copies: Four copies, \$1.30 each: Ten copies, \$1.20 each: Twenty copies and upward, \$1.10 each. These rates include Postage, in each case, which is pre-paid by the Publishers. Papers are addressed to each name.

The full Descriptions and Illustrations of the Premiums, with various Notes and Explanations, were published in 8 extra pages of our October number, which can not be repeated for want of space. Any one not having that number, can have one mailed, post-paid, for 10 cents; or a Premium Sheet only, will be mailed to any address without charge.

PREMIUM
Explanatory Notes.
N. B.

Read and carefully Note the following Items: The Table, on page 401, tells the name and cash price of each article, and (in last column but one), gives the number of names sent in at the regular price of \$1.60 a year that will secure any premium article. (The last column gives the number of names at the lowest club price for 20 or more names, that is \$1.10 each, but only a part of the premiums come under this head. Some persons quickly raise large clubs by taking all the names at \$1.10 each, and themselves pay the difference, 50 cents each, and even thus get the premium articles very cheaply.) (a) All subscribers sent by one person count, though from several different Post-offices. But... (b) Tell us with each name or list of names sent, that it is for a premium.... (c) Send the names as fast as obtained, that the subscribers may begin to receive the paper at once. Any one can have any time desired, up to next July, to complete any list, but every premium desired will be sent as soon as earned and ordered.... (d) Send the exact money with each list of names, so that there may be no confusion of money accounts.... (e) Old and new subscribers all count in premium clubs, but a portion at least should be new names; it is partly to get these that we offer premiums to canvassers.... (f) One or two Specimen Numbers, etc., will be supplied free, as needed by canvassers, (when 3 cents per copy is furnished to pre-pay postage), but they are expensive, and should be used carefully and economically, and where they will tell. Other specimen numbers will be sent, post-paid, to canvassers only, for 10 cents each. The price to others is 15 cents.... (g) Remit money in Checks on New York Banks or Bankers, payable to order of Orange Judd Company, or send Post-office Money Orders. If neither of these is obtainable, Register Money Letters, affixing stamps both for the postage and registry; put in the money and seal the letter in the presence of the Post-master, and take his receipt for it. Money sent in any of the above ways is at our risk; otherwise it is not.

Premium Articles for Sale.
It often happens that persons, who have not time to secure these valuable and useful premium articles by raising clubs of subscribers, are desirous of purchasing one or more of them, and wish us to procure or select them. For the accommodation of such, we will supply and send most of these premiums for cash, at the prices in the Descriptive List, and prepaid or otherwise, as stated.

Interesting Announcement!
125,000 MICROSCOPES.

Genuine, Well Made, serviceable, highly useful as well as interesting Instruments. A good source of instruction and amusement. Three Fine Lenses and Diaphragm—Stand with Glass Stage, Clips, Glass plates and Cell—Uses Reflected and Transmitted Light, or Opaque and Transparent Objects—Seven Different Powers—Magnifies 6 to 25 Diameters, and 36 to 625 Areas—Conveniently arranged for Practical Use—Not moulded glass, but carefully ground and thoroughly made Lenses.

ONE FOR
Every Subscriber
TO THE
American Agriculturist.

We have a very pleasant announcement to make. It has been customary of late years for many journals to annually present their readers with a Chromo, and this journal has done its part in sending out beautiful pictures that now adorn hundreds of thousands of homes. We have for months been looking earnestly for some other Souvenir, some Keepsake, to send to our readers, that would be not only interesting, but really and eminently useful to all, and WE HAVE FOUND IT!

After examining many things, it occurred to us that one of the most desirable, interesting, and practically useful things would be some convenient form of the Microscope, if a good one could be had within the limits of price, etc. A Microscope is really valuable to Farmers—to detect, distinguish, and aid in remedying diseases on plants and animals, whether from insects, decay, or smut, mildew, lice, scab, etc.; to detect adulteration in seeds, and their degree of goodness or badness, the proportion of fertile and infertile seed; also adulteration in fertilizers, ground bone, etc.; to examine wounds and bruises, extract slivers from the hands, etc., etc. The Microscope is equally useful to Gardeners, Florists, Fruit-growers, etc., for most of the above purposes and for many others.

To All Classes, the Microscope is useful to detect adulterations in food, as in coffee, tea, spices, sugar, and to examine the texture and defects of many articles.

As a source of Instructive Amusement, the Microscope is exceedingly valuable to Children, to Young People, and to grown people.

Impressed with the value and desirableness of an instrument which would accomplish the above, we set about examining the various low-priced Microscopes and magnifying glasses to be found here, or imported. Two difficulties were met with. First, the cheap instruments found, were all of poor quality, and lacking some facilities in working; and, second, anything having the perfection of lens and other parts which we could commend, would cost far too much to be introduced into every family. We found no microscope costing less than \$2.75 having the principal requisites of one we desired to find—such as triple lenses, stand, adjustability to use reflected and transmitted light, etc., etc.

Next, the query came up: Is it not possible, by means of improved machinery for grinding lenses, and for making each part, and by doing this on a very large scale, to get the desired Microscope at such an exceedingly low cost that every one of our readers could have one? To this end, we entered into consultation with the

Bausch & Lomb Optical Company, the inventors and manufacturers of the Excelsior and higher grade Microscopes, and of many other optical instruments, who enthusiastically seconded and aided our efforts to the utmost of their skill and ability. A large number of experiments have been made, many forms and combinations of lens and stand, etc., have been constructed, machinery has been devised for rapid and perfect work, and as the result, we have A MOST VALUABLE MICROSCOPE, which we now place before our readers with a satisfaction that is certainly very great to us, and will doubtless be pleasing to every reader of this journal.

Description of the Microscope.

The Microscope is shown in the engravings herewith, figure 1 representing it with the lenses separated. The three Lenses (a, b, c, fig. 2) are of superior glass, carefully ground, adjusted to use separately and in combination, and each one is in a polished hard rubber setting. The lens a (Fig. 2) magnifies about 6 diameters or 36 areas or surfaces; b magnifies about 8 diameters or 64 areas; c magnifies about 10 diameters, or 100 areas; b and c, used together, magnify about 18 diameters, or 324 areas. The three used together magnify about 25 diameters, or 625 areas. Used singly, or in combined pairs, and triplet, SEVEN different magnifying powers are obtained, of from 6 to 25 diameters, or from 36 to 625 areas. It will thus be seen that by using all three lenses upon a minute object or part of an object, its surface or area will be magnified or expanded 625 times!

Fig. 1.—MICROSCOPE WITH LENSES SEPARATED.

A Diaphragm, d, is used to cut off distortion and render the field of observation distinct. (Full

Fig. 2.—STAND—LENSES—DIAPHRAGM.

explanations of the use and mode of using each part, with many illustrations, to aid all to the proper

management of the instrument, will accompany each microscope sent out.)

The Stand (fig. 2,) has a base, s, of polished hard rubber, with an opening to admit light underneath. In the top of the base is a fixed glass stage, z, upon which to place objects to be examined. Two thin plates of glass are provided to lay over this, between which flat objects may be placed. The water-proof Cell, with a central aperture, can be placed between the glass plates, forming a cavity for liquids, for small insects, seeds, etc., etc. These plates and cell are held firmly in place by the Metallic Clips or Springs, so that the instrument can be set on the table or held in the hand for opaque objects, or be held up to the light when examining transparent or other specimens which are best seen by light passing through them.—The whole is inclosed in a neat Case or Box, with cover, for carrying and keeping. (Engravings of the different parts were given last month; and they will be found on the descriptive sheet sent with each Microscope.)

No instrument so well made, so complete and desirable, has hitherto been offered to the general public at so low a price as \$2.50. With the improvements in mode of manufacture, and the great number contracted for, this instrument will be supplied at retail for only \$1.50.

BUT to every actual subscriber to the American Agriculturist for 1878, one of these Microscopes will be supplied complete for 40 cents above the subscription price, when taken at the office or its delivery provided for. The Publishers pay for the additional cost of manufacture—a large sum in the aggregate.

(The American Agriculturist will be sent post-paid from receipt of subscription to the end of 1878. The Microscopes will be delivered as provided below.)

HERE ARE THE TERMS:

One Subscription and One Microscope.....\$2.00
2 Subscriptions and 2 Microscopes.....\$3.80 (\$1.90 each.)
3 Subscriptions and 3 Microscopes.....\$5.25 (\$1.75 each.)
4 Subscriptions and 4 Microscopes.....\$6.60 (\$1.65 each.)
5 to 9 Subscribers and 1 Microscope each.....\$1.60 each.
10 to 19 Subscribers and a Microscope each.....\$1.55 each.
20 Subscribers and a Microscope each.....\$1.44 each.
Or, in clubs of 20 and upwards, \$1.10 for each subscription, and 33½¢ for each Microscope, (that is, \$1 extra for every three Microscopes, in all clubs of twenty or more.)

Delivery of the Microscopes.

(Read all the Following to avoid Mistakes.)

I. Any Subscriber for 1878, will receive the Microscope on calling or sending for it at the Office, 245 Broadway, without expense, save the small payment of 40 cents above stated, which is only a part of the actual cost of manufacture alone.

II. Whenever there is a club of subscribers at any place, one of their number can be appointed to receive the Microscopes for all, and have them come by express, making the cost of carriage but a few cents each. We will pack them safely without charge, and forward them in any way directed, on receipt of the names for whom they are to be supplied, with the small extra sum for the Microscopes stated above.

III. Until otherwise announced we will undertake to deliver them to any part of the United States, and Upper and Lower Canada, on receipt of 15 cents for each Microscope, for payment of carriage.

IV. Our subscribers in foreign countries, not named above, will need to provide for, and direct how the Microscopes shall be forwarded to them.

Any Subscriber already on our books for 1878, can have a Microscope by remitting 40 cents, (adding the 15c. more, if to be sent prepaid.)

N. B.—The Microscope is designed for all subscribers on our books for the American Agriculturist for all of 1878, no matter from whom received, on the receipt of 40 cents—the Microscopes to be taken at the office; or 55 cents, if to be sent prepaid, except to foreign countries, as named above.

To non-subscribers the Microscopes will invariably be \$1.50 each, and cost of delivery if we deliver it.

MRS. OLD FOGY DOES NOT USE THE ROBBINS WASHER.

MRS. COMMON SENSE DOES. TAKE YOUR CHOICE.

TO MAKE MONEY SECURE AN AGENCY

FOR THE

CELEBRATED

ROBBINS FAMILY WASHER.

This machine has been ON TRIAL for the past six months in every State and Territory in the Union, and the almost unanimous verdict of housekeepers is this: "Your Washer has proved a complete success." Some of the reasons why this popular verdict has been reached may be found in these facts:

The Robbins Washer is an entirely NEW MACHINE. It is constructed upon a NEW PRINCIPLE—that of forcing water by downward pressure through the fabric. The dirt or discoloration is removed by water force—there is no rubbing or friction about it. This principle is the only one that has ever been successfully applied to the cleaning of fabrics by machinery. All others have failed in one or more essential points. The Robbins Washer will cleanse perfectly, without rubbing, all kinds of wearing apparel, table or bed linen. It will not injure the most delicate fabric. It is the greatest bleacher extant, and for this purpose alone is worth ten times the price of the machine. It is simple, self-operating, never gets out of order, and will last a lifetime. It saves time; it saves labor; it saves material.

By purchasing a ROBBINS WASHER you can count the hard drudgery of the washboard among the things of the past.

Therefore, we confidently say to every housekeeper in the land, You want a ROBBINS WASHER. You cannot afford to be without one. It will pay you to buy one.

THE RETAIL PRICE IS ONLY \$3.50.

Sample to those desiring agencies, \$3.

In bringing the Robbins Washer before the public it becomes necessary to take into brief consideration the

ART OF CLEANSING FABRICS,

which, although so common, is yet imperfectly understood. Having had a lifelong experience in the laundry business—in connection with first-class hotels, public laundries, asylums, hospitals, &c.—we know whereof we speak. The numerous devices of friction rollers, pounders, squeezers, dashers, agitators, steam wash boilers, &c., have all done very well, so far as it was possible for such principles and devices to do. But they have all failed in one or more of the three essential points, viz: The saving of labor, the wear and tear of clothes, or in perfectly extracting the dirt or discoloration—all of which are accomplished by the ROBBINS LITTLE WASHER.

WHAT IS IT THAT REMOVES THE DIRT?

You may ask all washerwomen and housekeepers, and your answer from nine out of ten will be: "Plenty of elbow grease;" or, in other words, plenty of hard, laborious rubbing on the washboard. And such is the case, for you first have to rub soap upon the cloth, then you have to rub it in to make the dirt soluble. But does that remove it? No; to do that you must first dip it in the water, and then rub it in again to force water through the fabric. That is what removes dirt after being softened by the chemical action of the soap upon it.

The way in which this could be the most economically accomplished is what we have so long and patiently sought after, and at last a principle has been demonstrated that in uniting all the above named, in

THE PRINCIPLE OF THE LITTLE WASHER

is embodied all the essential points. First, we have the desired heat, which expands the fabric and causes it to discharge the dirt. Second, we obtain a powerful suction beneath the clothes, which causes a rapid downward current of water force through and through them, thereby removing the dirt. Third, we use a large body of water, which holds the dirt in solution. Thus we cleanse thoroughly, rinsing the clothes as usual being all that is required to complete the operation.

The Washer is composed of solid galvanized iron, which will not rust or corrode. There are two sizes—the No. 1, or family size, for ordinary household use; and No. 2, or hotel size, suitable for country hotels, boarding-houses, laundries, &c.

OUR METHOD OF HANDLING.

We want agents everywhere throughout the United States, in every State, county, town, and hamlet. The retail price of No. 1 Washer is \$3.50, of No. 2 Washer, \$5. But we sell sample machines of No. 1 size at \$3; No. 2, or small hotel size, at \$4. Canvassers for this Washer can make more money with it than with anything ever before offered to the public. As, for instance, we established two agencies to test the sale of the Washer upon its merits—one in Naugatuck, Conn., and one in Providence, R. I. The former, Mr. Charles Daniels, in a town of about 2,000 inhabitants, sold by canvassing in two weeks eighty-two Washers. In the latter place Mr. James Roberts, now of Naugatuck, Conn., sold in less than three months, without canvassing or advertising outside the store, over 500 Washers. A thing never before heard of.

TO PERSONS OUT OF EMPLOYMENT

we would say, if you want to secure a paying business, now is your time. Don't wait till the best territory is taken up, but send at once for sample machine and go to work. By following instructions you can sell to nearly every family in your neighborhood. Others have done it, and there is no reason why you should not. Full directions and instructions accompany each machine. Also, special terms to agents, circulars, testimonials, &c.

All orders must be accompanied with cash.

Remit by money order or registered letter to

THE GEO. D. BISELL COMPANY,
Naugatuck, Conn.

STOCKBRIDGE MANURES.

Originated by Prof. STOCKBRIDGE, Professor of Agriculture in the MASSACHUSETTS AGRICULTURAL COLLEGE.

These manures are made according to the analysis of plants for different crops, and as they supply what the crop removes, they do not exhaust the soil, but actually leave it richer by their strong chemical action on the same, besides producing wonderful results. They have been extensively used for FIVE YEARS, and were

Used in 1877 on over 10,000 Acres with Great Success.

The Great Stock-Breeders' Monthly!

THE NATIONAL
LIVE-STOCK
JOURNAL,

PUBLISHED AT
CHICAGO, ILL.

Is everywhere acknowledged to be the Standard Authority upon all matters pertaining to HORSES, CATTLE, SHEEP, SWINE and the DAIRY. It is published monthly, each number containing from 44 to 48 large pages, printed on fine book paper,

nicely bound and HANDSOMELY ILLUSTRATED. It has an ably conducted VETERINARY DEPARTMENT, and during the year furnishes a great deal of valuable information on all kinds of live stock. No Farmer or Stock Breeder can afford to be without it. SUBSCRIPTION PRICE, \$2.15 PER ANNUM, POST PAID. Posters, handsomely illustrated with fine engravings of live stock, mailed free to all who will get up clubs, and a liberal commission allowed.

Address letters, registering those containing money, unless in shape of Postal Order or Draft, to STOCK JOURNAL COMPANY, Publishers, Lakeside Building, CHICAGO, ILLS.

BUTTER COLOR.

After fair trial and severe tests it was awarded Centennial Prize Medal. WHY IT IS SUPERIOR TO ALL. 1st. It has no taste or smell, and is as harmless as water. 2d. It is light, is easy to handle, and is mixed in cream by churning. 3rd. It produces a color resembling June Grass Butter. 4th. It is the only article that will color the butter and not the buttermilk. 5th. It gathers all butter materials, increases the weight more than will pay for the color used. It is the best ever known. Send your address on postal card for my receipt book, free. It tells how to make butter, pack, preserve, extract rancidity.

MRS. B. SMITH, 327 Arch St. P. O. Box 1954, Phila., Pa.

LILLY'S BUTTER-WORKER

The cheapest and best Machine in the market; no hard labor required. Try it, and see for yourself. Only \$15 for a thirty pound machine that will take all the milk out with five minutes' work.

HENDERSON & CO.,
316 Race St., Phila., Pa.

Serviceable Silver-Plated Ware.

"Silver Steel" and "Albata" Silver-Plated.
Save the retailers and jobbers profit, and buy direct of Manufacturers at Wholesale Prices.

An opportunity is now given to buy any of the silver-plated ware manufactured by us direct. The goods are made of good durable metal and will wear for years.

These are not cheap brass goods, like the so-called "Premium Silver Ware," with which the market is flooded, but are warranted as represented. Remember, brass goods are poisonous!

- We will pay postage on small packages by mail on receipt of the price.

| The entire set (50 pieces)..... | \$11.00 |

Since our former advertisements appeared, we have decided to give the readers of the *American Agriculturist* a higher grade of goods than those heretofore advertised. Not that the others did not give perfect satisfaction, but we feel that the new designs (made expressly for this trade) will, in quality and finish, be more desirable, and well worth the small advance in price.

All sums over \$1 should be sent in Registered letter.

Take it Easy.

Common-Sense Chairs and Rockers.

My Reading and Writing-Table is separate from chair, and is secured in position by a strong button. Is easily adjusted to nearly all kinds of arm-chairs, but should be used on my No. 4, 5, or 13, to give complete satisfaction. Table can be set at any angle desired, or lowered to good position for writing. Makes a nice table for an invalid. Cutting-board for the ladies. None of your little 7x9 affairs; but is 16x32 inches. Cannot be got out of order.

If Dealers don't keep my Chairs and tell you they have others just as good, don't believe them.

See that my name is stamped on chair before purchasing.

Nothing better or more suitable for

Chicopee Falls, Mass.

THE
"Model Piano."
PRICE \$150 to \$200.

The "MODEL" is a beautiful little Upright or Cottage piano; it is manufactured from the best materials that can be procured; the workmanship is excellent, and its durability is guaranteed; it is small, light, and occupies but little room, is easily transported, and above all the "MODEL" is sold at about one-third the price that is usually paid for any other reliable piano. For the above reasons, it is very suitable for people of moderate means, and those living in small houses; but it is especially adapted for beginners, and on account of its low price, commends itself to every parent, because it possesses all the principal features of the finest piano, and has none of the numerous disadvantages of the cheap organ.

For full particulars write for illustrated pamphlet, and state where you saw this notice.

Big Giant Corn Mill, Every Man His Own Miller.

The only Mill that will grind Corn with Shuck on without extra expense. The only Mill grinding Corn and Cob successfully that will grind Shelled Corn fine enough for family use. Grinds twice as fast as any other Mill of same size and price.

MANUFACTURED BY

J. A. FIELD, SON & CO.,
922 N. 2nd St., St. Louis.

IXL Feed Mill.

This mill is the cheapest, most durable and perfect iron feed mill ever offered. It is simple, easily managed, and can be run by Wind, Steam, Water, or Horse power. The chilled iron plates have grinding surfaces on both sides and can be reversed, thus making one set equal to two on the old plan. An extra set is sent with every machine, and the two sets will grind Four Thousand Bushels of good Feed. New plates can be had for \$1.25 per set. These mills are built wholly of iron, (except the Hopper,) are strong, efficient, and durable. Thousands are in use on Stock Farms—every one giving excellent satisfaction. Every farmer should have one and grind his own Feed.

THE

GLOBE NAIL.

THE BEST HORSE SHOE NAIL EVER MADE.

About ten years ago the GLOBE NAIL COMPANY of Boston, put on the market the first pointed, polished and finished Horse Shoe Nails ready for driving. Previous to that time all Horse Shoe Nails were pointed, and most of them made, by the shoers in their own shops at the rate of but six pennies per day.

The Globe Nail was at once found to be much cheaper and better than any then in use. It soon became so popular that all manufacturers of Horse Shoe Nails were compelled to make their Nails to resemble the Globe. For the last ten years it has been the model. Each year the Nail has been greatly improved in quality, and to such a point have we educated the shoers that now they will hardly use a nail unless it is absolutely perfect.

600 lbs. Finished Nails per day.

At the Centennial Exposition in Philadelphia, we were awarded the Medal and the following report, far stronger than that given upon any other Nail:

INTERNATIONAL EXHIBITION, 1876.
U. S. CENTENNIAL COMMISSION.

[BUREAU OF AWARDS.]

PHILADELPHIA, June 22, 1876.

No. 239, Globe Nail Co., Boston, Mass.:

Horse Shoe Nails, Pointed, Polished and Finished. The uniformity in size, smoothness of finish, hardness and tenacity of the iron, closeness of fibre, and excellence of the head and point, the tensile strength of body, and riveting properties of these Nails, unite in making them of the very highest class of manufacture.

Recommended for an Award of Merit.

DANIEL STEINMETZ, Phila., Chairman,

J. D. IMBODEN, Richmond, Va.,

CHARLES STAPLES, Portland, Me.,

G. L. REED, Clearfield, Pa.,

DAV. MCARDY, Aberdeen, Scotland,

T. DIEFENBACH, Germany,

Group
Judges
XV.

We annex a sample of the testimonials we receive daily from all parts of the country:

ST. LOUIS, Mo., June 8, 1877.

GLOBE NAIL CO., BOSTON, MASS.
Gentlemen: Find enclosed advertisement and postal card concerning your Nail. (Referring to a scurrilous advertisement and postal card, disparaging the Globe Nail, circulated by a rival manufacturer over the humbug signature of "Humane Society for the Prevention of Cruelty to Animals." No Society bearing that title ever existed.) As I take a great interest in the prevention of cruelty to animals, —horses in particular,—I desire to say a few words in favor of The Globe Nail. Though I am not a very extensive Horse Shoer, yet I have used enough Nails of the different makes to speak knowingly. I have used the Globe Nail in my shop and on the race track for six years, on all classes of horses, from the heavy draft horse to the tender footed running horse; and I can safely say it has no superior in point of Toughness, Shape, and Finish, if it has any equal. I have used about fifteen hundred pounds of Globe Nails a year for the last six years, and in that time I have found four imperfect Nails, two of which I returned to you about two years ago and received in return four perfect ones, for which accept my thanks. If my men had no better sense than to drive those imperfect Nails in a horse's foot, I would not consider it the fault of the Nail if the horse was lamed. If bosses would look more to the competency of their men and less to trying to get shoeing nails a few cents a pound cheaper, we would have fewer lame horses. I know for safety and durability, with a man who understands his business to drive them, your Nails can't be beat. I am willing to pay, without any suit, for all horses that are lamed in my shop by using the Globe Nail. As long as it is made as at present, I shall continue to use it, even if I could get other Nails for nothing. I consider it the safest Nail that was ever driven in a horse's foot.

Yours Very Respectfully,

(Signed,) P. H. O'NEILL.

Horse Shoer, No. 1007 Broadway.

P. S.—I think I could get every boss in St. Louis to sign this if I thought it necessary.

P. H. O'N.

The best Horse is sure to win, SO
CLEAR THE TRACK FOR THE

GLOBE NAIL CO.

"ECLIPSE" FARM ENGINE.

HIGHEST CENTENNIAL AWARD and SPECIAL MENTION by the U. S. CENTENNIAL COMMISSION.

A MEDAL AND TWO DIPLOMAS.

INTERNATIONAL EXHIBITION, PHILADELPHIA, 1876. No. 235.

The United States Centennial Commission has examined the report of the Judges, and accepted the following reasons, and decreed an award in conformity therewith:

REPORT ON AWARDS.

Product, Portable Farm Engine. ("Eclipse.")

Name and address of Exhibitor, Frick & Company, Waynesboro, Pa.

The undersigned, having examined the product herein described, respectfully recommends the same to the United States Centennial Commission for Award, for the following reasons, viz.:

This engine gives the best results of any that were tested, and may be regarded as a well-made, strong, and useful machine. The traveling wheels are large and powerful. The boiler is suspended on springs for traveling, which are let down when at work. The boiler is capacious. There is a powerful brake on the hind wheels, very useful for staying the engine when at work. The engine is carried on the top of the boiler, resting on a powerful bed-plate, which is hollowed out to form a receptacle for oil leakage. This can be detached from the brackets, and the engine converted into a fixed horizontal engine if required. The governor has three speeds, and the crank shaft is counterbalanced. The engine saddle has provision for varying expansion. The water heater is large, of the ordinary diaphragm form, and the pump with air chamber is well constructed. The cylinder has balanced slide valve. The safety valve works by a spring, which is a good arrangement, particularly when the roads are rough. Driving wheel on each side of crank shaft.

THE GREAT AMERICAN TEA COMPANY,
P. O. Box 5643. 31 and 33 Vesey St., New York City.

W. S. BLUNT'S UNIVERSAL FORCE PUMPS.

Secured by letters patent.

These pumps have enormous power, and are for the house or for out-door wells of any depth. They are constructed with special regard to strength, ease of working, and durability. They can be immediately changed from lift to force pumps, and the air chamber can be removed, so as to allow the handle to work at any desired angle with the spout. Having close tops, they cannot be tampered with. Attention is called to our new elegant pattern **DEEP WELL non-freezing FIRE PUMP.** Also, Blunt's Sand Vacuum Chambers.—A complete protection against sand or gritty water in dug or driven wells, pits, mines, and rivers. For hand or steam pumps, all sizes, from 1½-inch to 4-inch suction pipe.

Send for circulars to
NASON MFG CO.,
71 Fulton and 71 Beekman St., New York.
Western Agency, Newton & Hale, Chicago.
Pacific Coast Agency, Dunham, Carrigan & Co., San Francisco, Cal.

HALLADAY STANDARD.

The only wind-mill awarded **TWO MEDALS** and **DIPLOMAS** by the Centennial Judges. Acknowledged by all to be the best made, the most perfect self-regulator, the most powerful and the most durable wind-mill known.

Every Mill Guaranteed as above.

Each piece fitted and numbered at the Factory, so that farmers and others can erect their own mills if desired, using our drawings and instructions for a guide. Send for Illustrated Catalogue & Price List.

SAW MILL FOR THE PEOPLE.

THIS patent portable Mulay Saw Mill is adapted to any locality, will saw any kind of logs, and will do as much work (power and hands being considered) as the best Circular Mills. Its frame, head-blocks, and working parts are of the most substantial and permanent kind, being made entirely of iron and steel. It is usually set up and started in from one to two days time. It is generally driven by thrashing engines of not exceeding ten horse power. It cuts from 2000 to 4000 feet of inch lumber per day. The Mill and Engine may conveniently be operated by two men. Send for circular.

INDIANAPOLIS, IND.

NOW IS THE TIME TO APPLY

FOR AN AGENCY FOR

C. & G. Cooper & Co's Traction

OR

SELF-PROPELLING FARM ENGINES

By a simple but effective attachment made to our common farm engines, we are able to offer a **Traction or Self-Propelling Farm Engine**, which not only propels itself, but hauls a water tank and separator over any road, up hill or down, with the aid of one pair of horses.

This engine is a complete success, having been thoroughly tested for two seasons. Nearly one hundred of them have been sold the last year, and all are giving the best satisfaction. They cost but little more than the common farm engine, and enable the thrasher to operate with from two to four less teams, and to move much faster than with horses. Circulars, containing cuts, descriptions, prices, and testimonial letters from our customers, furnished to thrashers, free, on application.

Agents Wanted in every County in the wheat-growing States. For Circulars and for Agencies, apply to

C. & G. COOPER & CO., Mt. Vernon, O.

THE "DOMESTIC" ENGINE.

BACK VOLUMES OF

American Agriculturist.

The publishers of the *American Agriculturist* can supply any of the back volumes of that paper from the Sixteenth to the Thirty-sixth. These volumes contain more varied and interesting information on all matters pertaining to the Farm, Garden, and Household, than can be obtained in books costing three times as much money. Price of each bound volume, at the Office, \$2.00; sent post-paid, \$2.30.

Good Times

FOR

BOYS and GIRLS.

CRANDALL'S BUILDING-BLOCKS.

Can be made into forms of almost endless variety.

The blocks are put up in neat, strong boxes, and a large sheet giving various designs of buildings, etc., accompanies each box.

Price—No. 1, \$1.50; by mail, prepaid, \$1.80.
No. 3, 75 Cts.; by mail, prepaid, 90 Cts.

CRANDALL'S MASQUERADE-BLOCKS.

Making 300 different and beautiful Combinations of Pictures, which are in very brilliant colors. They are not injured by washing, do not wear out, and afford endless amusement.

Price 75 Cts.; by mail, prepaid, 90 Cts.

CRANDALL'S EXPRESSION-BLOCKS.

With Letters on one side, Picture on the other. The Alphabet is the key to the picture which, when complete, represents the inventor in Dream Land. These Blocks are water-proof, and can be washed if soiled.

Price 50 Cts.; by mail, prepaid, 65 Cts.

CRANDALL'S ILLUMINATED PICTORIAL ALPHABET CUBES.

These Cubes are gorgeously colored, and will make over 500 beautiful combinations or figures. They are water-proof, odorless, and durable; put up in handsome black walnut boxes; and are most attractive to both young and old—an elegant present for the little ones.

Price \$2.50; by mail, prepaid, \$2.80.

CRANDALL'S IMPROVED GYMNASTS.

Two jolly little fellows, attached to opposite ends of two bars, are made to perform the most laughter-provoking antics, and to throw themselves into the most unaccountable positions, by gently working the foot of the wooden frame through which the bars revolve. It is a low-priced toy, made on the principle of the "Little All-right," and like that one of Crandall's latest. It is not conveniently sent by mail, but for sale by most Toy-Dealers.

[SEE ALSO FOURTH COVER PAGE.]

N.B.—If postage is not remitted with the prices, as above, the blocks will be sent by express at purchaser's expense.

Orders from the trade will be supplied on liberal terms.

ORANGE JUDD COMPANY.

245 BROADWAY, NEW YORK.

INSTRUCTIVE. BEAUTIFUL. AMUSING.

CRANDALL'S BLOCKS FOR CHILDREN.

The Best Presents Ever Invented for Boys and Girls.

Crandall's District School.

Every child, and man and woman too, will laugh over this group of teacher and scholars in the "district school," and thousands of parents will recall with great delight their own experiences in childhood. The grave "master," seated by the desk, with his "whisking stick"; the boys and girls with their books; the "little lamb" that has followed his young owner into the school; the "dance" and his cap, and the altogether comical appearance of the whole company, make this one of the most attractive toys of Crandall's invention.

Price per Set, \$1.00; by mail, prepaid, \$1.20.

Crandall's Heavy Artillery.

The greatest amusement of the age! Recreation at home for all ages, and for all seasons! Crandall's Heavy Artillery is made up of a large Cannon, complete, which throws a 1½-inch Rubber Ball to the distance of 25 feet or more, and Sixty Blocks (Red, White, and Blue), to build up Fortifications, also a Company of Soldiers, with Officer and Flag, to garrison the Fort. The Game is to beat down the

Fort by the use of the Big Gun. Rules, Illustrations of a variety of Forts, etc., accompany each box containing the set, and the box is 18 inches long, 6 inches high, and 8 inches wide.

Price per Set, \$3.00. Expressage to be paid by the recipient.

Crandall's Wide-Awake Alphabet.

No more long faces and no more tears over A B C! Here we have amusement and instruction combined. Each box contains twenty-seven little men, each representing a letter, with arms, legs, and jolly faces. This set of Blocks is susceptible of more changes, and a greater variety of forms and combinations than any Spelling Block ever offered to the public. The Pieces are durable, the Letters plain, the Faces mirthful, and the Amusement afforded by them unlimited. They please while they instruct, and are a source of enjoyment to young and old.

Price per Box \$1.00; by mail, prepaid, \$1.30.

Crandall's John Gilpin.

This beautiful and interesting toy is regarded by Mr. Crandall as one of the best of his inventions for the little folks. It is made up of two figures, John Gilpin—whose highly colored dress is especially attractive to Boys and Girls—and his Horse, which intelligent animal performs a very important part in the illustration of Gilpin's famous ride.

Price per Box \$1.00; by mail, prepaid, \$1.25.

Crandall's Menagerie.

One of the most wonderful and amusing things ever brought out for the entertainment of children. The six animals composing the Menagerie are beautifully painted, and so arranged into 56 pieces in each box, that tens of thousands of most laughter-provoking figures can be made up with them.

Price \$2.00. By mail, prepaid, \$2.50.

Crandall's Alphabet-Blocks.

RED, WHITE, AND BLUE.—Tasteless, odorless, and water-proof. The letters are on red, white, and blue ground. All children are pleased with them.

Price 75 Cts.; by mail, prepaid, 90 Cts.

Crandall's Toy Horse.

Here is something that will make glad every little boy who gets it. The Toy Horse is about 6 inches in height to the tops of his ears. He stands upon a four-wheeled base, all ready to be set in motion by his owner. He is made up in pieces and can be taken apart and laid snugly away in his box.

Price 25 Cts.; by mail, prepaid, 30 Cts.

Crandall's Acrobats.

Full of fun and frolic, and most brilliant in costume. These are among the most fascinating and ingenious toys ever invented. The number of figures which can be made with the pieces in a single box is limited only by the ingenuity of the operator.

Price \$1.00; by mail, prepaid, \$1.20.

"Ye Hero of '76."

The great "Patriotic Toy." A fine old soldier in a brilliantly colored uniform, with cocked hat, staff, and flag, all put up in a neat box. The Hero is so constructed that he can be placed in almost numberless and amusing positions, and will delight the children everywhere.

Price 25 Cts.; by mail, prepaid, 30 Cts.

Crandall's Little All-Right.

One of the funniest and jolliest of the low-priced toys. The lively Little All-Right throws himself into a great variety of positions as he whirls around the "wheel." This toy can not conveniently be sent by mail. It is one of the latest things manufactured by C. M. Crandall. Ask the nearest Toy dealer for Crandall's Little All-right, hasten to buy it, and be happy.

ORDERS from the TRADE will be SUPPLIED on LIBERAL TERMS.

ROBBINS WASHER.MRS. COMMON SENSE
DOES.
TAKE YOUR CHOICE.

TO MAKE MONEY SECURE AN AGENCY FOR THE CELEBRATED ROBBINS FAMILY WASHER.

This machine has been ON TRIAL for the past six months in every State and Territory in the Union, and the almost unanimous verdict of housekeepers is this: "Your Washer has proved a complete success." Some of the reasons why this popular verdict has been reached may be found in these facts:

The Robbins Washer is an entirely NEW MACHINE. It is constructed upon a NEW PRINCIPLE—that of forcing water by downward pressure through the fabric. The dirt or discoloration is removed by water force—there is no rubbing or friction about it. This principle is the only one that has ever been successfully applied to the cleaning of fabrics by machinery. All others have failed in one or more essential points. The Robbins Washer will cleanse perfectly, without rubbing, all kinds of wearing apparel, table or bed linen. It will not injure the most delicate fabric. It is the greatest bleacher extant, and for this purpose alone is worth ten times the price of the machine. It is simple, self-operating, never gets out of order, and will last a lifetime. It saves time; it saves labor; it saves material.

By purchasing a ROBBINS WASHER you can count the hard drudgery of the washboard among the things of the past.

Therefore, we confidently say to every housekeeper in the land, You want a ROBBINS WASHER. You cannot afford to be without one. It will pay to buy one.

THE RETAIL PRICE IS ONLY \$3.50.

Sample to those desiring agencies, \$3.

In bringing the Robbins Washer before the public it becomes necessary to take into brief consideration the

ART OF CLEANSING FABRICS,

which, although so common, is yet imperfectly understood. Having had a lifelong experience in the laundry business—in connection with first-class hotels, public laundries, asylums, hospitals, &c.—we know whereof we speak. The numerous devices of friction rollers, pounders, squeezers, dashers, agitators, steam wash boilers, &c., have all done very well, so far as it was possible for such principles and devices to do. But they have all failed in one or more of the three essential points, viz: The saving of labor, the wear and tear of clothes, or in perfectly extracting the dirt or discoloration—all of which are accomplished by the ROBBINS LITTLE WASHER.

WHAT IS IT THAT REMOVES THE DIRT?

You may ask all washerwomen and housekeepers, and your answer from nine out of ten will be: "Plenty of elbow grease;" or, in other words, plenty of hard, laborious rubbing on the washboard. And such is the case, for you first have to rub soap upon the cloth, then you have to rub it in to make the dirt soluble. But does that remove it? No; to do that you must first dip it in the water, and then rub it in again to force water through the fabric. That is what removes dirt after being softened by the chemical action of the soap upon it.

The way in which this could be the most economically accomplished is what we have so long and patiently sought after, and at last a principle has been demonstrated that in uniting all the above named, in

THE PRINCIPLE OF THE LITTLE WASHER

is embodied all the essential points. First, we have the desired heat, which expands the fabric and causes it to discharge the dirt. Second, we obtain a powerful suction beneath the clothes, which causes a rapid downward current of water force through and through them, thereby removing the dirt. Third, we use a large body of water, which holds the dirt in solution. Thus we cleanse thoroughly, rinsing the clothes as usual being all that is required to complete the operation.

The Washer is composed of solid galvanized iron, which will not rust or corrode. There are two sizes—the No. 1, or family size, for ordinary household use; and No. 2, or hotel size, suitable for country hotels, boarding-houses, laundries, &c.

OUR METHOD OF HANDLING.

We want agents everywhere throughout the United States, in every State, county, town, and hamlet. The retail price of No. 1 Washer is \$3.50; of No. 2 Washer, \$5. But we sell sample machines of No. 1 size at \$3; No. 2, or small hotel size, at \$4. Canvassers for this Washer can make more money with it than with anything ever before offered to the public. As, for instance, we established two agencies to test the sale of the Washer upon its merits—one in Naugatuck, Conn., and one in Providence, R. I. The former, Mr. Charles Daniels, in a town of about 200 inhabitants, sold by canvassing in two weeks eighty-two Washers. In the latter place Mr. James Roberts, now of Naugatuck, Conn., sold in less than three months, without canvassing or advertising outside the store, over 500 Washers. A thing never before heard of.

TO PERSONS OUT OF EMPLOYMENT

we would say, if you want to secure a paying business, now is your time. Don't wait till the best territory is taken up, but send at once for sample machine and go to work. By following instructions you can sell to nearly every family in your neighborhood. Others have done it, and there is no reason why you should not. Full directions and instructions accompany each machine. Also, special terms to agents, circulars, testimonials, &c.

All orders must be accompanied with cash.

THE "Model Piano."

PRICE \$150 to \$200.

The "MODEL" is a beautiful little Upright or Cottage piano; it is manufactured from the best materials that can be procured; the workmanship is excellent, and its durability is guaranteed; it is small, light, and occupies but little room, is easily transported, and above all the "MODEL" is sold at about one-third the price that is usually paid for any other reliable piano. For the above reasons, it is very suitable for people of moderate means, and those living in small houses; but it is especially adapted for beginners, and on account of its low price, commends itself to every parent, because it possesses all the principal features of the finest piano, and has none of the numerous disadvantages of the reed organ.

NEW SERIES—No. 373.

A VERMONT CHEESE FACTORY. — Drawn and Engraved for the American Agriculturist.

Upon subsequent pages, we have quite liberally illustrated the internal arrangement, and the appliances of a cheese factory, and to complete the series, we give above an engraving showing the exterior of a Vermont Factory, from a sketch by an artist of that State. The introduction of the factory system into a farming neighborhood, not only quite changes the mechanical operations of the dairy, but has a marked effect socially, upon the farmers themselves, and their families. Under the old system each worked by himself, in his own way, with but little reference to what his neighbors were doing, and rarely comparing his results with those of others. The factory changes all this, and by at once establishing a common interest, creates a community of thought and feeling; it becomes absolutely necessary that the neighbors should meet and discuss, to compare methods and ask advice; it leads to reading, and a general increase of intelligence and mental activity. In those States in which dairying is an important branch of farming, there are already Associations of Dairymen, who hold annual conventions, which are often attended

by their wives and daughters. It is no disparagement to other similar gatherings, to say that we have never seen a gathering of farmers any where that seemed to be more thoroughly respectable, intelligent, or manifested more interest in the matters before them, than those we met at a meeting of the Vermont Dairymen's Association. The factory system divides the business of dairying into two important branches, viz: The production of milk, and the making of cheese, and each presents numerous subjects for consideration, which require accurate practical and scientific knowledge in discussing them. The annual conventions, held in various parts of the country, at which all the topics related to both branches of the business are thoroughly discussed, have already produced excellent results, manifested in increased profits, and a considerable improvement in the quality of the products. At these meetings the addresses and discussions are in part by farmers and factorymen themselves, and in part by teachers of scientific agriculture and chemistry. But besides these annual conventions, there are all over the country, and of

daily occurrence, informal meetings, the discussions at which have an important influence upon the business of dairying. Such an informal dairyman's meeting is suggested in the engraving; the farmers who daily supply milk to the factory, meet there in small groups. On such occasions the talk is of the business in which all have an interest, and cows, feed, milk, and management are discussed, hints are given and experience told, and in the long run these informal meetings are quite as valuable as the larger ones; indeed, this intercourse, and mutual instruction, this bringing farmers into frequent contact, is one of the useful incidents growing out of the factory system, and which extends its good influence among the farmers to matters other than the dairying. Weights and a balance on the right side of the account book are convincing arguments, and the farmer who can point to a heavy balance in his favor, will find his associates ready to learn his method of managing his animals. While the cheese factory is profitable as an industrial institution, it is at the same time an educational one, that is practical and useful.

AMERICAN AGRICULTURIST.

NEW YORK, FEBRUARY, 1878.

"The oldest inhabitant" does not remember a winter that began so favorably as the present one. To plow on the last day of the year, with the weather like that of May, while the cows are pasturing on the meadows, is, for the Eastern and Northern States, something remarkable. Fortunately, there has been little harm done by the extraordinary mildness of the early winter; and much of the spring work has been put in a very forward state. This is a great help; a farmer, unless he can be ahead of his work, must labor under many disadvantages. Of all men, the farmer most lives for and works for the future. He plows and sows, months before he reaps. His young stock always appear to him as the future matured animals, and it is of these that he thinks, and not the young creature which he feeds and nurses. He must plan for years ahead; when he breaks up a sod he has in his mind's eye the field again in grass five or six years hence, and the work of all those years is to insure a good meadow then. No man needs to be more patient than he, nor to wait more cheerfully for good or ill, he knows not which, that may befall him. And now that winter seems hardly to have begun, we are already anxious about the spring, which will be at hand in a month, and plowing what shall be done about this or that. The management of properly regulated farms should be planned, once for all. There should be no changes, except those regularly recurring which arrive year by year, and which follow one another as orderly as the changes of the seasons. The great fault of American farming is this constant desire for change. We change our farms as we would change the fashion of our coats. We rarely think of them as homes which our children shall occupy after us. It is the same with our stock, crops, and manner of farming. As the fashion comes up, or any new thing or idea is talked about, we cast aside, or leave the old, and take up the new. We do not take time to learn the value of what we have, or that there is good in every thing, if we only persevere and bring it out. We take up dairying, for instance, trying all the popular breeds of cows, and leave that to take up hops, tobacco, or fruits. Then we go to grain-growing, and finally begin to think the West, or the South, or orange-growing in Florida, is more desirable, and try to sell out; in the meantime we give no heart to our

business, and that necessarily languishes. There are many exceptions, but this is the rule. We hear it talked over wherever farmers gather, and read of it in reports of farmers' clubs, and conventions. This is unprofitable. The farmer should be conservative, steady, patient, persevering, and contented, if he would be a successful and happy man. While the whole world depends upon him for food and clothing, he can never fail to have profitable employment, or find a market for his crops. The best farmers are those who discover what their farms are best fitted for, what they can do the best, and persevere in that—year by year becoming more proficient, more experienced, and more successful.

Hints for Work.

Seeds of All Kinds should be procured at once. Seed dealers are overrun with orders just when farmers want the seed to sow, and the chances are, that these wants can not all be supplied at a day's notice. Those who buy seed at home, sometimes have to leave their work in the field and hunt up seed from their neighbors, who, having sold the best, have only the refuse left. Prices are always higher just at sowing time. The man who must have an article, is in the power of the seller.

Procure Good Seed.—Fresh plump seed, free from seeds of weeds, should be procured, even if it costs much more than old and foul seed. There is no economy in buying poor seed, but a great loss; and care in selection will be well repaid.

Feeding Stock is the most important labor of the winter season, and intimately related to this is

Making Manure, which is, or should be, carefully considered in feeding stock, and where the quality of the manure-heap is carefully looked after, the stock will always be well and profitably fed.

Rich Manure can only be made from rich food. Animals add nothing to the manure. If we feed straw, we get back as manure something less than the straw we feed, and straw alone is very poor manure. If we feed oil cake meal, corn meal, bran, and similar rich food, to mature animals, they consume the starchy and fatty portions, while much of the nitrogen and phosphates go into the manure heap along with the straw or hay eaten, which give the needed bulk to the manure. The more nitrogen the food contains, the richer will be the manure. It is thus that the statement made by chemists, that the manure made by feeding a ton of bran, or linseed, or cotton seed oil cake, is for some soils worth more than the food itself, can be satisfactorily explained.

Oil Cake is the refuse of the manufacture of linseed and cotton seed oil. Many thousands of tons of it are made in this country yearly, but it is almost all exported to England, where the farmers feed it to fattening animals for the sake of the manure. The use of this rich food is to be highly recommended, and were it properly understood and appreciated, not a ton of it would leave this country.

Bran and Middlings may be fed to all kinds of stock. All, from horses to poultry, eat these eagerly, and thrive upon them.

Corn Stalks and Straw should be cut up with a fodder cutter if only to be thrown into the yard, or used for litter. Short stalks absorb more liquid than long; the manure from them is easier handled, and they rot more quickly. A fodder cutter run by a two-horse tread power, will cut 100 pounds of straw, or stalks, in five minutes, and the cost of the machine and often labor will be repaid in one season in the convenience of handling the short manure.

The Manure Heap may be made in a central place in the yard, and the different kinds of manure should be wheeled out of the stables and pens, and mixed together in the heap. We find it pays to turn over the heap once or twice during the winter, mix it thoroughly, and break up all the lumps. This makes it fine, and fit for use early in spring.

Manure is Wasted by exposure to washing rains, or by being trampled by stock in wet yards. It may easily lose three-fourths of its value in this way.

Manure that has been Drawn Out during the fine fall weather should be evenly spread, and not left in heaps, otherwise the places covered are too rich,

All About California.—Those of our readers who desire reliable information in regard to the Pacific Coast, should get the "S. F. Weekly Bulletin," advertised in our columns. Its reputation is first-class in all respects. It is a good literary and family paper, as well as a faithful exponent of Pacific Coast facts. Mr. J. W. Simonton, the well known Agent of the Associated Press, is one of the principal owners of the "Bulletin."

and the rest of the ground does not get its share. We see many fields now dotted over with heaps, hauled out in December. Leaving them until spring, is one of the small leaks which help to make greater ones.

Watering Stock is a very important part of the care needed for them at this season. Empty and clear the troughs of ice every afternoon, so that when filled in the morning there is no ice to chill the water. In cold weather water should not be drawn from the well until it is needed for the stock. Covers should be provided for all outside water troughs to keep out snow.

Clear away the Ice from watering places, gates, and all places where cows would be in danger of slipping; many a calf is lost by reason of cows falling upon icy places. If nothing else can be done, scatter upon the ice some coal-ashes, or sand, which will thaw in during sunshine and will freeze on to the surface at night, and make it rough.

A Smoke House may be prepared and set up ready for use next month, when bacon and hams may be taken from the pickle. A store of corn cobs may now be saved for the smoking. A smoke house, 6 feet square, and 8 feet high, made of double boards, will be sufficient to cure a large quantity of meat by beginning early. Finish this work, and have the meat packed away safely before the flies appear.

Stone Boats.—A very seasonable work now is to procure some heavy plank, and make a stone boat for every team. One does not know how useful these implements are on a farm, until they are tried. To haul stone is only one of their many uses.

Harness will be greatly improved by taking it apart, washing with soap and water, and dressing it with some good water-proof preservative. We have used the "Tunyoap Water-tight," made by the Tunyoap Manufacturing Co., of Boston, for harness as well as for the soles and upper leathers of boots. It renders the leather soft and impenetrable by water.

Draining in wet swamps can be done all through the winter months with ease and comfort. We provide a plank about 12 feet long, either at the side of the ditch or in the bottom of it, to stand upon while working. This keeps the feet dry. But little frost penetrates swampy ground, even in the coldest weather, and if the surface that is partly dug is left loose at night, it can be broken up with ease. Contracts for ditching 2 feet deep, and 2 feet wide at the top, have been made for 25 cents a rod.

Grinding Feed is profitable. Ground feed goes farther in use than whole grain. Where the money can be afforded to purchase a mill, this can be done with profit where 10 head of stock are kept. A mill that will grind 4,000 bushels before it needs repair, can be bought for \$50, or less. There is a saving of 400 bushels in the shape of toll, and the time of going to mill besides. This latter will be about equal to the time taken up in grinding at home, and there will be left the value of the 400 bushels of grain for the \$50 spent, and the mill can be made as good as new at a small cost.

Young Stock.—To keep young stock growing through the winter, will hasten their maturity by half the time. A good thrifty 2-year-old that has had no set-back, will be equal in weight to a 4-year-old that has not grown during the winters. The cost of two years feed is saved by the expenditure of the little extra feed and care for two winters. This principle applies to all live stock.

Over-Feeding is a waste of food, and causes a loss of flesh. Indigestion from repletion, stops growth, and gives trouble to restore health and thrift. The art of feeding is an important part of a farmer's knowledge, and should be studied with care, and practised with patience and close observation. The use of weights and measures is not a waste of time and labor. There is much to be learned and saved by them. Every feed-box should have a one-quart and a two-quart scoop, and a feed measure holding a known quantity. A half-peck measure (4 quarts) is a handy size to have.

Feed Troughs and Racks should be provided for yard feeding, both for grain and fodder, so that nothing may be trampled under foot, and wasted, and strong animals may not drive off or annoy the

weaker ones. We can easily contrive so that the animals of all kinds must do precisely as we wish.

Separate Yards for feeding may be made by putting up a few panels of portable, or other fence, across the main yards. A few strands of fence wire, stretched from one side to the other, make a good division, and the snow does not drift against it.

Smutty Corn.—The wet weather of the past summer has caused much smut to grow in the corn. This fungus is poisonous to animals, and doubtless is the cause of much unexplained trouble. The smutty stalks should have been laid on one side in the field; but if not done, throw out now and burn. The dust of the smut is its seed, and, if permitted to escape, will perpetuate the pest.

Cows.—Preserve strict cleanliness in the cows' stables. Dry cows may be fed moderately to keep them in fair condition only. Heavy milkers, when near the time of coming in, need judicious treatment, so as not to unduly stimulate the secretion of milk. Milking cows should be kept warm. If the udders, or teats, become foul, they should be washed with warm—but not hot—water, and wiped perfectly dry at once. To wash the teats, and leave them to dry, will cause cracks; the same effect will occur if the teats are wetted with milk and left to dry. The teats should be kept dry while milking, if one would avoid cracks and sores.

Ewes and Lambs.—Light feeding of grain is preferable for ewes at this season. Too much corn meal will be positively injurious. Half a pint of corn a day will be sufficient, alternated with a pint of wheat, bran, or whole rye. A mixture of one quart of salt, and one ounce of sulphur, placed in a box where the sheep can always reach it, will be beneficial. Early lambs with their dams should have warm pens in sheltered parts of the stables during the coldest weather. Such pens are very useful for ewes that reject their lambs.

Young Lambs are troubled with few complaints; the chief of these is costiveness, which may easily be remedied by giving a teaspoonful of castor oil. New-born lambs should have a little of the oil applied to their hind parts to prevent the glutinous dung from closing the bowel. This should be looked for and guarded against, or remedied without delay.

Young Pigs that arrive this month need the best of care, or they will be lost. They are hardy animals after the first dangers are over, and they are able to help themselves. A stove in the piggery would be found very useful; or if a separate building, well warmed with a stove, could be provided for occasional use in the cold weather, many young animals might be saved that are now lost.

Poultry.—We find that it pays well to warm the feed for hens. It is a very easy matter to put a pan of corn in the oven over night, and have it warm for the morning feed. For the afternoon feed we put in the oven about noon a pan of cracked corn covered with water. When this has swollen, and soaked up the water, it makes excellent feed. Some of the Imperial Egg Food may be given twice a week at this season.

A Clean Poultry House is indispensable, if the fowls are expected to be healthy. It is a small job to scrape, sweep, and dust the floor, and remove the droppings twice or three times a week during feeding time. The droppings should not be stored in the poultry-house, but in a dry place, packed in barrels, and kept for use in the spring.

Sundry Matters.—It will be well to turn out potatoes that have been kept in barrels, or bins, to prevent sprouting. Potatoes have a tendency to sprout this season, and should be closely looked to.... Air the cellar thoroughly on a cool dry day to lower the temperature; 35 degrees is warm enough for a vegetable cellar.... Clean machines, washing the gummy parts with kerosene oil, and wiping them off with a bundle of rags dipped in sperm oil.... Watch root pits closely, and see that the ventilation is ample and perfect. Roots are growing very much in the pits this winter in consequence of the mild weather. To prevent this, we have opened the pits at the bottom by thrusting in a sharp-pointed bar every two feet, and letting in cold air to reduce the temperature.... Ice should be gathered as early as

possible. Late ice is not so solid as that gathered during the short days when the sun has little power to soften and make it porous.... To preserve health, keep the feet warm and dry, the throat and chest well protected, and when warm with exercise avoid standing still, or cooling off suddenly. The last named precaution relates as much to working animals as to their owners.

Notes on Orchard and Garden Work.

If one near the end of a letter begins to talk about the weather, it is regarded as indicating that the writer is running short of ideas. To avoid any such suspicion, we put the weather at the beginning. What a winter this has been, thus far! We write on January 15th, and there have not been, we should judge, 15 days (12 miles N. and W. from New York City) in which late fall or early spring work could not go on in the open ground. The gardener or farmer who had not his fall work thoroughly done up this New Year's day, is not likely to ever have it so. Gossip about the weather is of but little use unless we can draw some lesson from it. Cultivators in this vicinity have paid dearly for one lesson—which is, that routine work will not always answer. Those who have followed their usual custom of covering up their pits of roots and their trenches of celery for the winter, on a given date, have learned that this is a not a safe practice. The losses from decay are said to be very general, where the full covering has been placed on stored vegetables, while those who postponed the covering until it should be found to be needed, escaped damage.... In protecting living plants, we notice that the practice has been much modified of late years. It is quite easy to kill a half hardy plant with too much covering; indeed it is not unlikely that many plants have the reputation of being "very tender," instead of "half hardy," because in the trials that have been made of them they have been covered too much. A clump of *Osmundus*, *Skimmia*, and other plants heretofore regarded as unsafe in the open ground in our climate, we have now in their third winter out. Pea brush is stuck around them, and enough salt-hay thrown in among it to shade the plants, but not sufficient to prevent circulation of air. They came through the last winter, which was a very severe one, unharmed. It is likely that with similar treatment, other plants which we feel obliged to house might be left out of doors. Strawberry plants are often killed by too thick a covering, under which they do not get fairly dormant. What the effect of this unusual weather will be upon peaches, and other easily excitable trees and plants, remains to be seen.

Orchard and Nursery.

Were we to devote the whole paper to it, we could not say all that might be said in any one department; hence we point out each month the important matters on which a novice is most likely to need a reminder. This month one may find occupation in earing for the old trees he already has, or in preparing to plant new orchards, and it may happen that he must attend to both.

Renovating Old Trees.—There is a popular notion that trees get into an unproductive condition through a neglect of pruning, and that a thorough pruning is all that is needed to restore them to a healthful and fruitful state. This is a mistake. While pruning is usually needed, this is not the chief want of the trees. They have been brought to their poverty by starvation, and their great need is food. This being supplied, pruning, scraping, and other treatment may come in to aid.

Manure being the first thing needed, the fertility of the orchard may be brought up by a generous application of barn-yard manure, spread upon the surface, and turned under by a shallow plowing. In the absence of sufficient manure, then green crops, buckwheat, or clover, may be sown, to be turned under, with application of lime, or ashes. Having provided for the soil, then

Pruning may be considered, if the variety is known to be a desirable one. In pruning an old,

or any other tree, it should be done with a definite object. If branches have been broken, or are partly decayed; if the head is so crowded that light and air can not enter; if limbs cross and chafe one another; if the head is quite one-sided, or if for any other reason a removal of a portion of the top will be beneficial, then use the saw.

Time and Means of pruning.—The preferable time is when severe weather is over, and before vegetation has started, which in the Northern States is generally the latter part of this, and the first part of next month. Use a pruning saw or other narrow-bladed saw, with the teeth set wide; smooth the wounds with a drawing knife, and then cover them with melted grafting wax, or thick paint.

Scraping and Washing the old bark is useful; sufficient is said about this on page 51. If the tree produces indifferent fruit then, besides the renovation already mentioned, it should be

Grafted with some good sort, but it will be of little use to graft an old tree if it is still to be starved. With a large tree, it is better to graft only about one-third of the head each year, beginning with the branches in the center of the tree. The time is just as the buds begin to swell. The mechanical operation was very plainly described, and fully illustrated, in April, last year. It is not practicable to repeat these elementary matters every year, and for this reason we advise every one who has an orchard and fruit garden to provide himself with a work upon tree culture. The back numbers may be procured for 15c. each. In planting new orchards, no time should be lost in making the

Selection of Varieties, if not already done, and in ordering the trees. In deciding what to plant, the disposition to be made of the fruit is to be regarded. If the fruit is to be for family use only, then the varieties should comprise those that will give a supply from the earliest to the latest. If fruit is for market, and to be shipped a long distance, then but a few sorts known as the best for keeping and shipping will be better than many sorts ripening at different times. Those whose orchards are near cities, find large and showy early fruit more profitable than late kinds. In selecting varieties, those not familiar with them will do well to consult the fruit growers of their vicinity; this advice will be of far more value than that of persons at a distance.

"Where Shall I Buy?"—is a question often asked of us, and to which we reply in general terms:—Buy only of nurserymen of established reputation—the cards of such are found in our advertising columns. A little extra freight, or a few cents in the price of a tree, is nothing when compared with the risk in purchasing of unknown parties. One must wait from 6 to 10 years for his trees to bear, and the chance of finding them all wrong at the end of this time, is one not to be taken. In a newly settled country one may profitably buy

Root Grafts, which are sold at some nurseries at very low rates. These consist of a part of the root of a stock, with the cion inserted and waxed in. The work is done in winter, and the grafted roots kept in earth in a cool cellar until spring. A thousand of these grafts will pack in a box of moderate size. They should be set out in spring as soon as the soil can be well prepared, in rows $3\frac{1}{2}$ feet apart, with the root-grafts 18 to 24 inches apart; the grafts, which should have only half an inch or so of the top above the surface, are usually set with a dibble, and care should be taken to have the soil well packed around the root. The ground must be kept clean, and the young trees kept to a leading stem the first year, in which they will grow from one to two feet high. In subsequent years, the cultivation should continue, the trees shaped as needed, and with three, or at most four years growth, they will be large enough to plant out. There need be but few failures, and in localities far from nurseries may be made a source of profit.

Mice and Rabbits are likely to be troublesome in localities where snows still fall. Prevent damage as suggested last month.

Insects must be looked after now. The clusters of eggs of the *Tent Caterpillar* may easily be seen against the sky in a dull day; they are to be looked

for as a ring about $\frac{3}{4}$ of an inch wide, near the ends of the twigs. Cutting and burning one of these destroys about 500 caterpillars. . . . *The Canker Worm* has unfortunately reached places where it was not known a few years ago. The insects come out of the ground in early spring—sometimes in February in a warm time—ascend the trees to lay their eggs, from which will come a devastating brood that will take every leaf. They are easily kept down, as the female is wingless, and has to climb up the trunk. A barrier applied early, and kept in good condition, will stop them. There are numerous contrivances; the simplest is a band of stiff paper applied closely to the trunk, to which is applied pine tar or printer's ink. These must be examined every few days, and the application renewed if not sticky, as sometimes dust and the bodies of dead insects make a bridge for the living insects to cross upon.

Fruit Garden.

The plants in the fruit-garden coming into bearing much sooner, and being watched more closely, the need of abundant manuring is more manifest here than with the slower growing and longer-lived trees of the orchard. What is said of the necessity of perfecting plans in advance, and preparing for planting under Orchard, applies here. The fruit-garden is for what are known as Small Fruits; if trees are admitted they should only be

Dwarf Fruit Trees.—We were surprised to learn from a usually intelligent merchant a few days ago, that he supposed dwarf pears were distinct kinds, and different from those upon large or standard trees. As others may have the same impression, it may be well to say that the dwarf pears, apples, etc., are made so by grafting or budding the ordinary varieties on a stock that controls and stunts their growth; this causes them to come into bearing very young, and to be very fruitful in proportion to their size. The pear is grafted on a quince stock, to dwarf it, the apple, for the same purpose, on a kind of apple called the Paradise. There are also dwarfing stocks for cherries, plums, etc., and there are two or three peaches that are natural dwarfs.

Shall We Plant Dwarf Trees? has long been discussed by fruit-growers. With the exception of a few pears, the conclusion is that for profit they are of but little value, but if one wishes to grow many varieties on a small space, or for ornament, they possess much interest for the amateur.

Pruning may be done on dwarf trees, and if grapes, currants, gooseberries, etc., were not finished last fall, they should be pruned on mild days.

Supports are needed by blackberries, for which we use a stake standing about 6 feet out of the ground; some give them a wire trellis, such as we use for raspberries, but higher. This kind of a support is made by setting a strong stake, or small post, at each end of the row; a heavy galvanized wire is attached to a post by one end, and the other is fastened to a piece of $\frac{1}{4}$ -inch iron rod, upon which a screw thread is cut; this rod passes through the other post, a nut put on, by the turning of which the wire is tightened; a washer is put between the nut and the post. The vines are tied to the wire.

For Grape Trellises in a small vineyard, we prefer the upright wires. Posts are set 8 feet apart, a strip $2\frac{1}{2}$ inches wide nailed on a foot from the ground; a corresponding strip nailed above this at the top of the posts; the distance (and height of the posts also) being governed by the length one chooses to grow the canes; some have it but 3 feet, others 4 feet, or more. The arms of the vine are fastened to the lower strip, and a perpendicular wire, fastened by a twist to the lower and upper strip, is placed for each shoot. When one wishes to train his vines in this manner, this is an excellent trellis. But a grape vine is so tractable that it will accommodate itself to almost any situation, and supports should be made ready in advance, and if to be painted, this may be done before hand.

Kitchen and Market Garden.

The difficulties in keeping stored roots, where unusually mild weather has prevailed, have been alluded to; this weather must also unfavorably affect

Plants in Cold-Frames, which have thus far required the sashes but a few days this season, and it has been almost impossible to maintain the dormant state so necessary to their proper wintering. Beyond thorough exposure, and shading where practicable, during sunny days, the gardener can do nothing to counteract the weather.

Hot-Beds, for starting early plants, will be required in the warmer States. The rule is to make the bed six weeks before it is usually safe to set plants in the open ground; consequently the earlier the season opens in any locality, the sooner should this preparation be begun. In these Notes for February of last year, the matter was treated in full detail. Our space now will allow of only a brief summary.

Cold-Frames and Hot-Beds are the same in all respects, save that the latter is warmed by a layer of fermenting manure. In an article on Cauliflowers, page 63, Mr. Henderson sufficiently describes a cold-frame. It is used for keeping cabbages, lettuce, and other nearly hardy plants, through the winter, and to forward plants in the manner referred to in the article. Besides these, the frame may be used for sowing seeds, and though the results will not be so early as in a hot-bed, some weeks may be gained. By exposure to the sun during the day, and covering the sashes before the heat declines in the afternoon, the interior can be kept quite warm. For a hot-bed

Sashes, Frame, and Manure are needed. The usual size of sash, 3 x 6 feet, with five rows of 6 x 8 glass, set in rabbeted bars, which run lengthwise—there being no cross bars, but the glass is lapped about $\frac{1}{2}$ inch, without putty at the lap. These sashes are sold at the factories glazed or unglazed. The frame is built in a pit, $2\frac{1}{2}$ feet deep, 6 feet wide, and of a length to hold the number of sashes. The pit is lined with rough boards, nailed to posts, and which extend above the surface of the ground a foot at the rear and 4 to 6 inches at front. Slats should be provided from front to rear where each pair of sashes meet, to guide the sashes and to hold them when pushed part way down.

The Manure may be all stable manure, or mixed with one-half more or less of leaves. It should be in a heating state, and put into the pit with coarse and fine equally distributed, beating the layers down with the fork, and when full, tramp the manure down level. Spread on 6 inches of rich soil (put under cover last fall), and place the sashes.

Sowing the Seeds.—The heat of the bed will at first be too violent, and the seeds must not be sown until it declines; when the thermometer shows about 80° it will be safe to sow the seeds, which should be in rows 4 inches apart, and running from front to rear. . . . We prefer

Sowing Seeds in Boxes, or flats, which are wooden trays about 2 inches deep, with bottom and sides securely nailed. They are made from soap-boxes and similar packages, one of which will make two or three. Where these are used, only 2 or 3 inches of soil are placed on the manure, and the boxes, in which the seeds are sown, are set upon this.

Care of the Bed must be thorough, as the neglect of a few hours will ruin all. The temperature should be kept as near 75° as possible; this is maintained by tilting or pushing down the sash when too warm, covering on cool nights; shading on hot days. Besides this care, which will be needed each morning and evening, and oftener in sudden changes, the plants must be watered, the soil stirred between the rows, and be thinned if too thick.

Window Boxes answer nearly all the purposes of a hot-bed for a family garden, in which the number of plants required is small. The boxes, or flats, already referred to, or other convenient box, will answer. A kitchen window is preferable to any other, as the air is usually more moist. Sow seeds in such window boxes, and when the plants are up, turn the boxes every day, to bring the opposite side to the light, and keep them from growing to one side. When the seedlings get two or three "rough" leaves, those beyond the seed-leaves, they should be "pricked out" or planted in other similar boxes, setting them an inch or more apart, according to kind. The young plants may grow in these

until time to put them in the open ground. Set the box out doors in the middle of every mild day, or open the windows, in order to harden the plants.

The Kinds Usually Sown in hot-beds, frames, and window boxes, are cabbages, cauliflowers, and others of that family; lettuce, tomatoes, peppers, and egg-plants; the last two will do a month later. Cucumbers, melons, and early squashes, may be started later, a few seeds to give plants enough for a hill, in a small box or 4-inch pot. The roots of these are large, and do not succeed in a small pot.

What to Sow.—We have in former years given a list of varieties that our experience has shown to be quite satisfactory; this year Mr. Henderson gives on page 62 his experience, which is much the same as ours. We always advise sowing the main crop of well-tested varieties, and while we advocate the testing of all the new things that one can afford to try, we regard it as highly unsafe to depend upon untried novelties for the family supply.

Where to Buy.—Look through our advertising pages, and send for catalogues. We do not commend one dealer in preference to another. We believe that all whose advertisements are admitted, will do as they agree. The low rates of postage on seeds, makes it unnecessary to regard locality; the distant purchasers can easily reach dealers, wherever they may be, and vice versa.

Seeds on Hand should be carefully looked over; while some are just as good as ever at the end of several years, others have a limited vitality. Onions, leeks, and parsnips should always be of the former season's growth. Beans, peas, egg-plant, carrot, okra, pepper, salsify, sage, and other sweet herbs, keep safely for two years. Radish, spinach, and parsley, are good at three years old. Cabbage, and all of its tribe, including turnips of all kinds, and celery, keep perfectly well for four years. Others seem to be quite as good at the end of five or ten years, as at first, such as melon, squash, and all that family, with beets and tomatoes. When in doubt about any seed, test it before time for sowing. Count out a dozen or twenty seeds, and sow them in a little earth in a cup, placed in a warm place, and the earth kept moist. If half or two-thirds sprout, it will be safe to sow the seeds.

Implements, Fertilizers, and whatever else is to be purchased, should be on hand before the hurry of the spring work begins....Get bean-poles and pea-brush before vegetation starts....Have extra parts to all implements liable to be broken.

Flower Garden and Lawn.

So much space has been given to other departments, that we may only say as to this that all preparatory work, such as planning new lawns, paths, and borders and selection of trees and shrubs for planting, should be done while there is yet leisure....Ornamental trees of all kinds, but especially evergreens, should be guarded against injury from heavy snow falls, by shaking the snow from the tops, and digging it away from the lower branches.

Greenhouse and Window Plants.

The increasing sun will bring many plants into flower, and at the same time encourage the insects, for the treatment of which quite full Notes were given in December last. Free use of tobacco smoke or tobacco water, where it is inconvenient to use smoke, will destroy many. A small collection of plants, tended by one really fond of them, may be kept free of insects by mere "thumb and finger work." Daily examination, the use of a stiff brush, like an old tooth-brush, and a pointed stick to pick off mealy bugs and scale, will keep insects from doing harm. Neglect to examine in time, and nip the trouble in the bud, is the cause of much of the difficulty. More water will be needed by plants in bloom and making their growth....Bulbs, if any remain in the cellar, may be brought to the heat and light. When the flowers fade on the earlier ones, cut away the stalk and let the leaves grow on; when they begin to fade, dry off the bulbs, which may be planted in the garden afterwards.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our daily record during the year, show at a glance the transactions for the month ending Jan. 12th, 1878, and for the corresponding month last year, and also for the year ending Dec. 31, 1877:

1. TRANSACTIONS AT THE NEW YORK MARKETS.

RECEIPTS.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.
25 d's this m'th	397,000	3,931,000	2,465,000	181,000	416,000	546,000
25 d's last m'th	473,000	4,116,000	3,491,000	383,000	1,312,000	1,407,000

SALES.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.
25 d's this m'th	313,000	4,104,000	3,513,000	159,000	311,000	839,000
25 d's last m'th	491,000	5,129,000	4,151,000	481,000	1,277,000	1,286,000

Comparison with same period at this time last year.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.

Gold has been up to 103½, and down to 102½, closing Jan. 12, at 102½, as against 103 on Dec. 12; 102½ on Nov. 12; 103 on Oct. 12; 105½ on July 12; 104½ on June 12; 107½ on May 12; 104½ on March 12; 106 on January 12, 1877....The Breadstuffs interests have suffered from various adverse influences during the month, and have shown serious depression, on a restricted volume of business, as well for home use as for export, closing heavily. Reports and rumors—especially toward the close—as to the probabilities of a restoration of peace in Europe, have been decidedly against the outward movement, which has also been unfavorably affected by the stronger range of ocean freights. Flour sales fell off to a very limited aggregate. Spring Wheat and new crop Corn closed moderately active at the reduced quotations. Winter Wheat generally dull, and quoted irregular. Within the month comparatively liberal export purchases have been made of choice White Wheat, and best No. 1 Spring, the latter in especial favor with buyers. Oats have been less freely dealt in, and left off weak. Rye and Barley have attracted less attention. The export call for Barley has been within narrow limits....A further material decline has occurred in Hogs and Hog Products, bringing prices down to the lowest prices in many years, influenced by the very free offerings here and at prominent points in the interior, particularly Chicago. At the reduced quotations, dealings have been on an extensive scale—in Lard and Bacon remarkably so for export. Beef and Beef Hams have been quoted about steady, but not active. Choice to fancy grades of Butter have been in good request at stronger rates; poorer qualities slow of sale and unsettled as to price. Cheese has been in fair demand at about former figures. Eggs have fallen off materially in price, closing weak; recent arrivals in excess of current requirements, and supplies accumulating....An active business has been reported in Hops, largely for export, within the quoted range....Cotton has been less freely dealt in at variable prices....Wool in fair demand, and held with confidence....Tobacco moderately sought after at about previous rates....Seeds generally quiet; rough flax wanted; values quoted, as a rule, steady. The exports of Clover Seed from this port, from Sept. 1 to Dec. 31, 1877, were 23,184 bags; and of Timothy Seed, 29,095 bags....Hay and straw have been in moderate demand, and prices have been fairly supported....A fairly active movement has been reported in Ocean and general cargo

freights, though checked, in part, by the stronger rates claimed by shipowners....Grain rates by steam to Liverpool closed on the 12th of Jan. at 9½d. to 9¼d.; to Glasgow at 9½d.; to London at 9½d.; to Bristol at 9½d.; to Hull at 9½d.; to the Continent at 9½d. to 10d.; to Liverpool, by sail, 8d. 8½d.; London, by sail, 8½d., per bush. Flour to Liverpool, by steam, 2s. 9d.; London, by sail, 2s. 9d., and by steam 3s. 6d. to 3s. 9d.; Bristol, by steam, 3s. 6d. per bbl. Provisions by steam to Liverpool, 40s. at 45s. per ton; Cotton by sail 1½d. to 1¼d., and steam at 1¼d. to 1½d. Grain, by sail, for Cork and orders, at 6s. 3d. to 6s. 4½d., and to Continental ports, 6s. 3d. to 6s. 6d.; Italian ports, 5s. 7½d. to 5s. 10½d. per quarter; to Lisbon, in ship's bags, 16 cts. per bushel; to Oporto, in shippers' bags, 7s. 3d. per quarter.

Bees.—The dullness of the market was never greater than at the close of 1877. The depression in general business, and the decreased consumption of beef is shown by the condition of the market. Formerly a matter of 200 to 250 cars of bees a day made no impression on prices, but sales briskly cleared the yards. The first week of 1878 offered a wonderful contrast, 13 cars one day, and 38 the next, barely met the demand, and when a few more cars arrived the next day after, down went prices. Fine, dry weather, and small receipts put up prices ½c. per lb., but the heavy receipts of the last week knocked the strength out of the market, and the advance was lost. The market closed very weak; some

good Colorado steers of 1,500 lbs., selling at 9¢. to dress 56 lbs. to the cwt.; good natives for 10¢. to 10½¢. per lb., 57 lb. to the cwt., and extra at 11¢. to 11½¢. for 58 lbs. to the cwt.

The prices for the past five weeks were as follows:

WEEK ENDING	Range	Large Sales.	Aver.
Dec. 17.....	8½¢ to 13 c.	9 @ 11 c.	9½¢ to 10 c.
Dec. 21.....	7½¢ to 12 c.	8½¢ to 11 c.	9½¢ to 9¾¢.
Dec. 31.....	8 @ 12 c.	9 @ 10½¢.	9½¢ to 9¾¢.
Jan. 7.....	7½¢ to 12 c.	9½¢ to 10½¢.	9 @ 10 c.
Jan. 14.....	7½¢ to 11½¢.	9 @ 10½¢.	9½¢ to 9¾¢.

Cows.—Good cows are in demand, and sell quickly at \$60 to \$90 for extra good milkers; fair cows bring \$50, and poor from \$30 to \$40 per head. Poor cows have sold with difficulty.... **Calves.**—The crowding on the market of unsalable stock has reduced prices very low. At one time the past month 2½¢. per lb. only was paid for grassers. Hog-dressed veals have been in good demand, and sell for 8¢. to 9¢. per lb.; poor veals sold for 5¢. to 6¢. per lb. live weight, and grass calves could hardly be moved at 2½¢. per lb. live weight at the close of our report....

Sheep and Lambs.—The market for this stock may be called dead; killed by overstocking. A great many sheep are carried over unsold. The only bright day during the month was when only 800 arrived and sold quickly at 4¢. per lb. advance on former rates. Heavy arrivals put the market back again. A notable example of extremes was offered by the exhibition of some poor Texans of 63 lbs. average, which sold for 2½¢. per lb., and some Canada Sheep of 160 lbs. average, some weighing 300 lbs., which sold for 6½¢. per lb. The market closed very weak at 4½¢. to 6¢. per lb. for fair to good sheep, and 7¢. per lb. for lambs, live weight.... **Swine.**—Dulness rules the trade. Some days no sales are reported, and prices are nominal. As we close this is the case for live hogs, quoted only at 4½¢. to 4¾¢. per lb. City dressed sold very low to move them; 4½¢. to 5½¢. per lb., was all that could be procured. Western dressed are held but not sold at 5¢. Jersey dressed slow at 5 to 6½¢. per lb.

Export of Farm Products in 1877.

The condensed, but very comprehensive tables on page 45, are prepared expressly for the *American Agriculturist* by a gentleman who daily, throughout the year, attends the N. Y. Corn Exchange to gather information, prices, etc. These tables will be found very interesting. The 5th table will be disappointing in the amount of exports of Breadstuffs. The exports of wheat and flour were less in 1877 than in 1876, notwithstanding the large yield of 1877, owing to the high rates maintained by speculators, and the holding back the crop for increased prices by the producers themselves. Should the war in Europe soon close, prices will probably fall. There is, however, a notable increase in the export of corn (nearly 10,000,000 bushels), also in Rye and Barley. There has been also a considerable increase in the shipment of Wheat and Flour since January 1, as compared with last year.

From May 1st, 1877, to January 11th, 1878, the export of BUTTER from N. Y. amounted to 16,471,407 lbs., against 10,193,300 lbs. for the same period the previous year.—CHEESE, 109,274,566 lbs., against 75,348,082 lbs. the previous period.

FRESH BEEF exports during 1877, from New York, Philadelphia, Boston, and Portland, Me., 101,971,501 lbs., valued at \$10,047,609.—LIVE CATTLE exported from same places in 1877, 20,057 head, valued at \$2,987,540. Total value of cattle and beef, \$13,035,239. Pounds of MUTTON, 2,114,240; value \$119,500. Live Sheep 13,176 head; value \$63,960. Total Export from four Ports, of live and dressed (fresh) Beef and Mutton in 1877, \$13,218,699. An increase of more than 600 per cent over any previous year.

DON'T FORGET THE GOOD PREMIUMS To be Got Without Money.

Let it be Remembered by all our Friends, that notwithstanding the offer of the fine Microscope to our Subscribers, as elsewhere described, our List of Valuable and Useful Premiums, is still in Full Force, and there is yet plenty of time for thousands to secure, by a little effort, one of these Good Things that have already delighted multitudes who have received them. **Begin Now.** This month of February is a capital time. If you have not received our Illustrated Premium List, please send for it. (See p. 73.)

containing a great variety of items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

Publishers' Notices, Terms, etc.—The Annual Subscription Rates of the *American Agriculturist*, postage prepaid by the Publishers, are: One Copy, \$1.00 a year; Two Copies, \$3; Three Copies, \$4.20 (\$1.40 each); Four Copies, \$5.20 (\$1.30 each); Five to Nine Copies, \$1.25 each; Ten to Nineteen Copies, \$1.20 each; Twenty Copies and upwards, \$1.10 each; Single Numbers, 15 cents, post-paid.—The above terms are for the United States and Territories, and British America. To the above add 14 cents extra per year for papers delivered by mail in N. Y. City, and for copies sent outside of the United States and British America, except to Africa, Brazil, British Honduras, the East Indies, and Mexico. For the last named five countries the extra charge is 38 cents per year, to cover extra postage; Single Numbers, 17 cents, post-paid.... Remittances, payable to Order of Orange Judd Company, may be sent in form of Checks or Drafts on N. Y. City Banks or Bankers; or P. O. Money Orders; or in Registered Letters, such letters to have the money enclosed in the presence of the Postmaster, and his receipt taken for it, and the postage and registering to be put on in stamps. Money remitted in any one of the above three methods is safe against loss. **Bound Volumes** from Vol. 16 to 36 inclusive, supplied at \$2 each, or \$2.30 if to be sent by mail. Sets of numbers sent to the office will be bound in our regular style for 75 cents (30 cents extra if to be returned by mail). Missing numbers for such volumes supplied at 12 cents each.—**Any Numbers** of the paper issued for 21 years past, sent post paid for 15 cents each; or any full year, sent unbound, for \$1.60.... **Clubs** of Subscribers can be increased at any time, at the club rates, if new members begin at same date as original club.

The German American Agriculturist is receiving large subscriptions from every quarter, indicating that the additions and improvements made in it are being recognized and appreciated. It is the only purely German Agricultural paper in the United States, and we intend, with the assistance of our English readers, to at least double its circulation during the present year. Please make known to your German neighbors the merits of the English *Agriculturist*, and that they can for the same price have the German edition, which contains all the engravings and valuable articles of the English edition, with the addition of a valuable Special Department, edited by the Hon. Fred. Münch.

Provide for Seed, Implements, Plants, etc., NOW.—It is bad planning to wait until just as anything is wanted, before securing it. This comparatively leisure month is the time to calculate what is going to be needed in April and May, to study up the advertisements and see what is offered: to correspond with dealers, get their catalogues and prices; to make up orders and dispatch them, and fix the time you want them surely on hand—putting the time far enough in advance to have no delay occur by freshets, bad weather, or accident, and get a positive promise that the order will be filled. The dealers will be better prepared with good articles, and taking time by the forelock, will be a great gain. See "Hints for Work," p. 42.

A Flea "as large as an Ox."—Our ideas of the size of a thing are wholly by comparison. The moon, when seen out in the clear sky, appears no larger than an 8 or 10 inch ring or disk. When just rising from the horizon, where it is seen in comparison with objects on the earth, it often looks to be twenty to fifty feet or more in diameter. The other day a gentleman called to say that our Microscope surely did not magnify 25 diameters, or 625 surfaces. Having two glass slides, each containing a dried specimen of a flea, we put one of them under the springs in his Microscope, and asked him to hold it up to the light, and say how large it looked.—

"About as large as a pig," he answered. We then held the other slide up near the Microscope, and asked him to look at this with the unaided eye, and at the one in the Microscope, alternately, a few times, and then asked how large the magnified one now looked.—"As large as an Ox," he promptly answered, and departed abundantly satisfied as to our statement of its magnifying power.—So well satisfied was he that he subscribed for five copies of the paper and five Microscopes to be sent to his friends. Any one can test this question by using two small transparent objects of about the same size, one in, and the other outside of, the Microscope.

Value of Devon Cattle.—The value of Devon cattle is again ascending. It was not to be believed that a favorite, excellent, and old-established breed could long remain in neglect, or become permanently unpopular. Our advice long ago to those whose circumstances were favorable for keeping Devons, was to buy them while prices were unreasonably depressed. The depression seems to have passed away, and prices are advancing, if we may judge from recent sales. A sale of 3 cows and a bull was recently made by Ex-Gov. E. H. Hyde, of Conn., to Mr. H. U. Weed, of Stamford, in that State, at the price of \$1,000. The animals were Fairy 17th, (947,) age 7 years; Fairy 26th, (1622,) 4 years; Gertie, (1697,) 3 years, and the bull Huron, (727,) age 4 years.

Need of Veterinary Education.—The value of live stock in the United States amounts to over one thousand millions of dollars, the aggregate number of farm animals being as follows: Horses & Mules...11,149,800 | Sheep...35,935,300 Cattle...27,870,700 | Swine...25,726,800 No other country in the world approaches these figures. But no other country, rich in live stock, is so ill provided with veterinary assistance as we are. Practically all this vast number of animals is without medical care, for the few practiced surgeons are entirely insufficient to the care of one-thousandth part of them. Millions of dollars are sacrificed yearly for want of competent medical assistance for cattle when ill. Veterinary schools are needed, and hundreds of competent practitioners.

Read the Advertising Columns.—We have several letters now before us, asking where pigs, fowls, seeds, fertilizers, machinery, etc., can be procured. We consider all the information of this kind that is given in the advertising pages sufficient, if those needing anything will only look there; and can not find room to repeat what is already plainly told elsewhere. Every page of the *American Agriculturist*, including the covers, is interesting reading, and should all be carefully examined every month. In addition to looking after what one may want, the reading of what others have to say, in offering their wares, etc., usually starts up some new idea in the mind of the reader.—When writing to any advertiser, always tell him in what paper his advertisement was seen.—Live animals can now be sent by express, for hundreds of miles, as well as merchandise.

Live Stock in Iowa.—The State Auditor, of Iowa, publishes a statement, showing the number and assessed value of the live stock in that State for the last ten years. This very interesting document gives a clear view of the steady increase of the wealth of Iowa in cattle, as well as the surprising decay of sheep growing. We give the figures for 1867 and 1877 as follows:

1867.	Value.	1877.	Value.
Cattle...683,109..	\$8,628,941	Cattle...1,452,546	\$14,898,841
Horses...343,593..	16,532,925	Horses...639,385..	20,100,263
Mules...17,237..	1,125,410	Mules...42,887..	1,670,154
Swine...776,412..	1,483,245	Swine...1,654,708..	3,899,301
Sheep...1,354,608..	2,084,476	Sheep...318,439..	345,827

Sore Feet on Cows and Calves.—"G., Grantland, Va. Cows are sometimes subject to a sort of fever known as aphthous, which is marked by an eruption of vesicles, or small blisters upon the feet, and between the claws of the hoof, and about the mouth and tongue. This disease is somewhat allied to the so-called "foot and mouth" disease prevalent in Europe, but is not nearly so malignant in this country as there. The cure is to wash the feet with soap and water, and apply tar, or a mild solution of carbolic acid in water, to the parts affected; and to give at the same time half an ounce of hyposulphite of soda daily to a cow, or half as much to a calf for a week or two, until the blood becomes healthful.

Good Corn and Flour Cake.—At the house of a friend this morning, we had some corn-bread, so-called, which was very palatable, and, as usual, we asked the "particulars" for our readers. It proved to be half flour, viz., one quart each of corn-meal and wheat flour; two beaten eggs; one tea-cup molasses; one tea-spoonful of soda mashed fine. Mix all together with sweet milk, soft, and bake in a quick oven. The "quick oven" generally has much to do with producing good cake or bread, if not too quick to spoil the crust.

About the Microscope.

Sundry Notes.

I.—Disappointment.—An occasional note of disappointment comes from some one who has not got into the way of using his Microscope, so as to understand and appreciate its real value. To such we will say that it is all and more than we have promised for it, or about it, and we hope they will persevere in learning how to use it until it becomes, what it ought to be, and can be, to all, a most valuable, most interesting, and most useful instrument. We know it may be made to every person, worth ten-fold the entire cost of both the Microscope and this Journal for a year, and in this we are confirmed by the united testimony of many scientific men and others, who have had long experience with microscopes of various grades.—To help the uninitiated, we first sent out a six-page description of its use. After the first few thousand, we added another slip with more minute simple directions (partly printed in Jan. No., page 9). Now we send with each Microscope a combination of both sheets and other additions, in a 14-column sheet. Let any one still failing to make good use of the Microscope, send for this 14-column sheet, if he has not received either this or the first two. See page 66.

II.—Delay in Sending Them.—Despite the constant pressing of the work at the manufactory, and the employment of all the careful help we can make room for, in dispatching the instruments, the care and labor required to send them accurately, with the multitudes of directions to pick out of subscriber's letters ordering them (often quite obscure and uncertain in specific directions), we have been from two to six days behind in filling several of the orders. Though we shall now keep pretty close up to daily orders, we ask our readers to always allow us a leeway of say 8 or 10 days from the reception of their letters to dispatch the instruments. Usually it will be but three or four days. The names and subscriptions must first be entered in the alphabetical mail books, next the paper mailed, and then the forwarders have to consult the express and other routes, pack them, enter them in two books, one for the express office, and take the receipts for them, etc., and this too, with calls for 800 to 1,500 a day.

III.—Who Can Have Them.—Every subscriber to the *American Agriculturist* for 1878 can have one of the Microscopes delivered free to him, in any part of the United States or Canada, on payment of 55 cents, or 40 cents if it be taken at the office, 245 Broadway. This is a good deal below the actual cost to us, but that we calculated upon at the start, though the expense and work is considerably more than we at first expected.

IV.—Through News Agencies.—Those who take their paper through News Dealers, can have the Microscope just the same as subscribers on our own books, if their news dealers will assure us that they have paid him for the paper through the year. We can not afford to supply it to those who take only an occasional number, or part of the Volume. In setting the price below the cost, it was based on a whole year's subscription.

V.—The Price to Non-Subscribers is invariably \$1.05, if delivered, or \$1.50 if taken at the office. Several who have larger microscopes, and have received one each as subscribers, have bought others at \$1.50 to be used by their children, by classes of pupils, etc., and call them very cheap. Such sales help out on the general expense.

VI.—A Loose Microscope—Remedy.—“*Paterfamilias*” writes: “....My large family of sons and daughters constitute a ‘Microscope Club’ of themselves, and keep the instrument in almost constant use. Continual wear has loosened the lens tube a little upon the upright shaft. How shall I tighten it?”—Press the tube in a little at any place, by inserting the point of a pen-knife between it and the rubber. Or, more simply, slip into the tube a very small fibre of silk, or cotton, obtained by untwisting and picking to pieces a bit of thread. The finest whole thread will be too large. Draw the fibre through the tube, and insert the upright.

VII.—A General Educator of the People.—A distinguished scientific gentleman, in a private note, says: “....Your Microscope is the finest thing in the way of a newspaper premium enterprise that I have ever seen. It will prove a general educator of the people, inciting them to observe and study the wonderful world of small natural objects everywhere around us, and lead them on to further investigation. It will thus not only awaken interest in an important way, but multitudes of cultivators will find it eminently useful in detecting causes of disease in plants and animals.”

Cross of Shorthorns and West Highland Cattle.—Mr. J. A. Cochrane, the well known breeder of Hillhurst Canada, has recently experimented with a cross of West Highland heifers with

Shorthorn bulls. The produce has been tested, and has been found very satisfactory. A steer 29 months and 10 days old was recently slaughtered; the live weight empty of food was 1,332 pounds, the dressed weight was 797 lbs. of beef; 73½ lbs. of hide, and 67 lbs. of tallow; total, 937½ pounds, or 73 lbs. to the 100 of live weight. While the weight is not equal to that of good specimens of the pure Shorthorn at that age, yet the small loss in dressing this half-bred proves it to be a very profitable cross. The steer was weaned at four months old, and since then was fed upon hay and turnips in the winter, and grass in the summer, until he was put up for stall feeding two months before he was slaughtered.

Progress of Settlement in Minnesota.—The St. Paul Chamber of Commerce issue a card containing statistics, prepared by the State Commissioner, by which is shown that the wheat crop for 1877 reached forty million bushels; the total assessment for 1850 was \$806,473, and in 1877 was \$218,855,743; there are 3,600 common schools, a school fund of 3½ millions of dollars, and the population, which was 5,330 in 1850, is now 675,000.

The Hessian Fly.—“J. A.” Henderson, Ky. The pest of the wheat plant is now operating destructively in many parts of the country. We hear of it in Michigan, Wisconsin, Canada, New York, Ohio, Pennsylvania, Tennessee, Kentucky, and localities between. It is a small two-winged fly, which lays eggs upon the leaf of the wheat in August or September. These eggs hatch into small white grubs, which descend to the base of the stalk, and there suck the juices, causing the wheat to turn yellow, or to die. Soon after the grubs change to pupae, very similar in color and shape to a flax seed, and these remain until spring, when they change to the mature fly. The fly then deposits eggs in May, but the larvae is too late to do much injury to the wheat. The “flax-seed” condition is entered in June, and in July the second brood of flies appear. The remedies are burning the stubbles immediately after harvest, or plowing them under deeply so as to destroy the pupae which may be in hiding; to sow late in the Northern States, so that the flies may have laid their eggs before the wheat appears above ground; rolling the young wheat, by which the eggs are crushed; sowing salt, soot, or fine lime upon the young wheat, by which the maggots are killed, and generally by good cultivation and fertilizing to stimulate the wheat so as to enable it to resist the damage.

The Travis Wheat Hoe.—“C. K. C.,” Oakland Co., Mich., sends the following statement of his experience:—I used a Travis wheat hoe on part of a field of winter wheat, early in May last. The field had already been harrowed, and clover seed sown on it. We hoed a strip through the field, leaving each side as it was. I have watched this strip closely during the summer. The ground on it was more soft and yielding, and the wheat had a ranker appearance. At harvesting we could see a plain difference. As we cut with the reaper directly across the strip, we could see that the straw was brighter and stronger, and the heads plumper than on either side. Our estimate was that it would yield twenty-five per cent more than the rest of the field. I believe it very important to give our wheat ground a thorough loosening in the spring, and if we ever equal the English farmers in producing wheat, we will have to resort to hoeing. The large yields of wheat of the last season demonstrates the fact that our soils will produce as large crops as theirs, if we give them a fair chance. I am satisfied that the hidebound condition of our wheat fields in the spring of the year, requires a thorough loosening, and the common harrow does not do it deep enough. Timothy seed had been sown with the wheat in the fall, and the hoeing did not seem to injure it.

Pipe for the Conveyance of Water.—“A. C.,” Carroll Co., Md. To convey water 1,000 feet with a fall of five feet only, the pipe should be 1¼-inch in diameter the first 500 feet, and one inch for the remainder. If smaller, the outlet flow will be very small.

Malt Combs, or Sprouts.—“L. D.,” Lonsdale, R. I. The sample sent is malt combs, or the sprouts from malted barley and oats. This is from a mixed lot evidently, there being oats, barley, cockle, and seeds of foxtail grass mixed with the sprouts. The malt has probably been made from a very inferior quality of grain having oats, cockle, and foxtail mixed with it. Malt combs, when clean, are a very nutritious food for milk cows, and are cheaper at one cent a pound than bran at one cent and a quarter.

A House for 200 Fowls.—“W. R. M.,” Morris Co., N. J. To accommodate 150 to 200 fowls, it would be best to have two houses, or rather one so divided in the middle as to make two with a door at each end. A very cheap and good house may be made of boards: 4 feet high at the back, 10 feet in front, 16

feet wide, and 36 feet long. The roosts should be made at the rear, and in the form of a ladder, sloping back from the floor to the roof. In the middle there may be a room for nest boxes. If the front, which should face the south, is of glass, it will be much improved. As large a yard as possible may be provided, and fenced with lath, so that the fowls may be kept in when desirable. The materials for such a house need not cost more than \$30, and \$12 additional for sash for the front.

Sundry Humbugs.

The Editors, who do not, of necessity, know much about the business affairs of the paper, can judge fairly of the character of the subscriptions by the editorial correspondence. One of the straws which show that we are receiving many new subscribers, is the Humbug correspondence. If soon after the beginning of the year, we receive a large number of letters relating to humbugs that have been exposed long ago, we are quite sure that a great many persons make the acquaintance of the *American Agriculturist* for the first time, and gratified to learn of a quarter where their complaints will

be listened to, we at once find our humbug budget rapidly increasing. It does not matter that the great majority of these complaints have been already noticed, they are new to those who send them, and we are glad to see them, as one of the indications that we are receiving new subscribers and making new friends. The old circulars of

“A DECISION AT LAST,”

that variously worded story of a supplementary drawing, in which people get gold watches and lots of jewelry—by paying for them. We have heretofore mentioned “Russell & Co.,” and “Hetherington & Co.,” as being mixed up in a way we could not understand. In all the cases, so far as we recollect, the “Decision at Last” circulars say that the “Gold Watches” and “Jewelry” are to be had by paying the assessment to “Russell & Co.,” but many applicants would get letters from “Hetherington & Co.,” referring to the same business. Lately, there appears the firm of “Clark & Co.,” who write to a correspondent: “We have been appointed by the Finance Committee, instead of Messrs. Russell & Co., to Ship the Goods, collect the Percentage money, and forward it to New Orleans.” Can it be that, like Odello’s, “Russell & Co.’s”

“OCCUPATION’S GONE?”

Those who have had no tickets in the “Consolidated Lotteries”—and the great majority of those who receive circulars have none—need not care whether “Clark & Co.,” or “Hetherington & Co.,” are other names for “Russell & Co.,” or who is who, in the matter. Some persons—in the chance of getting for \$15 (or any other sum) “Gold Watches,” and lots of “Jewelry,” “valued at \$150,” (or any other sum)—are willing to admit the statement of the circular, that “the interest you held in one of the Lotteries represented by the Committee on Unclaimed Prizes, has resulted in your drawing” so and so. Now, every one knows whether he had or did not have an “interest” in one of these lotteries. If he had no ticket or “interest” in any lottery whatever, every honest man knows that the circular does not mean *him*, and there’s the end of it. If one is tempted to accept a statement (that he had an interest in some defunct lottery) which he knows is not true, and sends \$15 (or any other sum) to get Watches or Jewelry valued at \$150 (or other sum), and gets these—and afterwards finds that the articles are not worth the money he paid, he must go somewhere else for sympathy. He may be disappointed, but as he was willing to take advantage of a statement he knew was not true—the verdict of every honest man will be—“Served him right.”

“THE ROYAL DOMINION GIFT CONCERT”

is new as to time, but old as to wicked ways. Can there be any graduates from the “Wyoming” and “Topeka” swindles running the thing? Though it exists under an “effete monarchy” it has all the airs and graces of a Gr-r-r-eat and Glor-r-ious Republic. Just as those “Wyoming” and “Topeka” chaps did, so does this “R-r-oyal” thing. It sends a private (lithographed) letter, to people in the States, informing them, if they will send \$5, for a club of five tickets, their names are booked for a prize *sure pop*. They may find some Americans fool enough to play the part of “stool

pigeons" in their swindle, but we are glad to know of some cases in which "the putty did not stick." We have devoted more space than usual

TO LOTTERY SCHEMES,

as they are the most fascinating of all forms of humbug. Many think that they are fairly conducted games of chance, and if they invest, they only "take their chances" with the others—while the fact is they have no chance at all. These lotteries are rotten through and through, and the prizes pretended to be drawn, are generally "put up jobs," and given out merely as bait to catch others. Let them alone in all their manifestations, of "Gift Concerts," "Distributions," "Legal Decisions," and every other form, shape and style.

THE "BUTTER-COMPOUND" CHAP,

whose powder will enable one to turn out no end of butter at "Four Cents a Pound" seems to have exhausted the "Great West" and to be working eastward. The butter stuff "takes its way" in just an opposite direction to Bishop Berkeley's "Course of Empire." The butter-compound man at one time hailed from a town in Ohio. Then Western New York was his dwelling place. At last he located in Hartford where we were sure we had him. One Hartford friend called on him and found the door shut, but with a hole for letters. He called again and again, but no butter-compound man could he find. Now the chap turns up in Middlesex Co., Mass., and within about 20 miles of "The Hub."—If we do not mistake the Massachusetts dairy people who pride themselves on the excellence of their butter, this "four cents a pound" fellow will have a hard time of it.

THE EXERCISE OF COMMON SENSE

in the matter will show its utter absurdity. The circulars of this butter-compound man, actually shout and shriek for people to come and buy his stuff, which will allow them to make butter at "four cents a pound," and the "best of butter," "which cannot be detected from pure cream butter." Just look at it from a business point of view; "the best of butter" retails in Boston any where from 50c. to \$1.25 per lb. But suppose we put the "best of butter" at the low price of poor butter, 20c. per lb., 100 lbs. would sell for \$20. It is claimed that it can be made for 4c. a pound, or \$4, leaving a profit of at least \$16 on every hundred pounds. If this could be clearly shown at the Merchants' Exchange on State Street, this butter powder man could raise a million of dollars in one day, to go into the manufacture of this butter. He could get independently rich in a year. Yet, instead of doing this, he sends out his circulars, fairly beseeching other people to get rich by buying his stuff at \$1 per box (to make 100 lbs. of butter) at retail, or \$6 per doz. Now, look here, farmers, isn't this just altogether, quite absolutely too thin? We do not understand the "glamour" which all such propositions seem to fix upon the eyes of ordinarily shrewd people. Hundreds fall under it, else these humbugs could not flourish. With regard to this "Butter Humbug," right in your own precinct, we call upon you gentlemen of the "Massachusetts State Board of Agriculture," and you gentlemen of the "Massachusetts Society for the Promotion of Agriculture," who are doing so much good in other directions, to take up this vile fraud upon your farmers. Skin it of all its specious fallacies, and show up its naked carcass as a thing to be avoided.

MEDICAL MATTERS

are duller than we have known them in a long time; even the old things seem to have lost their vitality, and the "7 Barks" chap offers premiums of cake baskets and things to those who make the quickest sales. Some of these medical chaps send out circulars with the taking titles of "The Art of Money Making," "How to Get Rich," and the like, but we soon come to the same old story—sell their stuff, and make money.... We may as well say here to one very earnest person, who, to judge from his long letters on many foolseap pages, must have been badly handled by various quacks, and wishes us to help him expose them, but gives no name and address, that this is not our style of doing business. If he, or any other, has a complaint to make, we must have a

FULL AND SUBSTANTIATED ACCOUNT.

We pay no regard to anonymous letters, and can not make these columns a medium through which to redress private grievances.... Our friend at Oakland, Ill., has fallen in with the enemy, and it is

THE SAME OLD, OLD STORY.

Having some pulmonary trouble, he writes to those quacks, who propose to send a "Recipe Free"—but they take care to accompany the recipe with a circular, saying that their recipe did not do its work, because the herbs, as kept in drug stores, were not fresh. Of course, it follows that the "Doctor" who sends the recipe, can furnish his medicine all right for \$3, or some other sum. This is one of the oldest of quack medicine tricks. Our Oakland friend seems to have thought that there was safety in a "multitude of counsellors," so he consulted

one quack in Rochester, and another in Philadelphia, each of whom wrote him a letter, which was in both cases the same, word for word, and both of the "Doctors" wind up with precisely the same P. S., except the slight changes noted in brackets, saying: "If you desire [if desired] and [you] will give [send] me your symptoms in full, I will prepare a [the] remedy to suit your special [exact] case."—Perhaps this may be taken as an illustration of the saying that "great minds run in the same channel," but more likely it shows that quacks everywhere are up to the same tricks.

DIPHTHERIA REMEDIES,

In our January number we gave the best possible suggestions we could in regard to Diphtheria, on page 25. On page 8 we advised those who "get an alarming circular headed 'Diphtheria, Suffering and Death,' to put it in the fire," etc. We have been called upon by a gentleman who issues a circular with a similar heading, who brings abundantly signed certificates from judges, clergymen, editors, and other prominent citizens, showing that the physician who gave the prescription for manufacturing the medicine he sells, is of the highest standing and character, and also in commendation of the medicine itself. We accept all these statements, and do not call them in question. The ground we take in regard to this and all similar advertised remedies, is this, that no medicine should be advertised and recommended to be used by the public at large, except under medical advice. We exclude all secret remedies of every kind from our advertising column, and invariably urge our readers to shun all such remedies, and to throw all medical circulars of every kind into the fire, without reading, and not have their fears or hopes worked upon. On these general principles, which we act upon always, we wrote what we did last month. Of the particular parties who applied it to themselves, we knew nothing until they presented the certificates above referred to. We have no reason to doubt that the medicine has cured many cases of Diphtheria, and for aught we know, may be the best remedy ever brought before the public; yet we say, neither this nor any other similar or other medicine should be offered to the general public, as this is offered, that is, as a Specific, or Sure Cure, or for universal use, without good medical advice. "What is one man's meat is another's poison."

Catalogues have come in so slowly that our acknowledgments are deferred until next month. Dealers in general, try to have their catalogues ready for February, and as we go to press on the middle of January very few have thus far reached us. To avoid disappointment, we will say that to be noticed in March, all catalogues must reach us by February 12th.

New Spring Wheats.—Mr. Pringle, of Vermont, whose success in producing new varieties of the potato is well known, has been quietly at work for some years past at improving varieties of spring wheat. By continued crossings and selections, he has succeeded in producing varieties, which if they do as well elsewhere, as upon his own farm, can not fail to be of great value. In size of head, and beauty of grain, they are really remarkable.

Maple Sugar.—It is impossible to make the finest product without observing the utmost cleanliness at every step. This should begin with collecting the sap, and the covered buckets made by C. C. Post, Burlington, Vt., will exclude all foreign matter.

The Florida State Fair will be held at Jacksonville on the 12th to 15th of the present month. Our old friend, Doctor J. C. Kenworthy, is President of the Society, and matters are likely to be lively.

Asbestos Paints.—One can not give a final opinion upon a kind of paint until it has been worn for several years. The Asbestos Paints made by the H. W. Johns Manufacturing Co., are a comparatively recent invention, and we have them under trial; thus far we can say that they promise exceedingly well; the colors are of pleasing tints; the paint dries with a smooth hard surface, and, what is of importance to those who use it, it covers well; we have used it upon old and somewhat weather-worn siding, and the man who applied it, being used to painting, called our attention to this fact. We shall use it upon various work, new and old, and report results.

Fine Chinese Primroses.—Whether the amateur has a greenhouse, or cultivates plants in a window only, nothing will afford him more satisfaction than Chinese Primroses. They have the fault of not being readily propagated from cuttings, but this is more than compensated for by the satisfactory results from seed. If one needs cut-flowers, the double whites are among the most useful of white flowers, but if one wishes to make a show on the plant, the single sorts are pre-

erable. With a good strain of seed, each plant as it comes into bloom is a surprise, as they present pleasing difference in foliage as well as in flowers. The finest single Chinese Primroses we have ever seen, were some raised by William Barkham, gardener at Hohokus, N. J., to Jos. Jefferson, Esq., who is eminent in more than one department of art, and whose rural tastes are manifested in Louisiana as well as in New Jersey. Mr. Barkham's plants have elegantly formed leaves, and flowers, some of which are two inches across, with beautifully crimped or fringed edges, and a large, bold, yellow eye, and show by their vigorous development, careful culture.

"Querist," Washington Co., R. I., and 1,492 others. If you do not care enough about your letters to sign them, it is just as well not to write them. New subscribers should understand, what our old friends are well aware of, that we do not notice anonymous letters. We do not publish names, if a wish is expressed that we should not do so. This can be done by signing the letter with whatever name you choose, but the real name must be given to insure attention.

Bommer's Method of Making Manure.—"G. G. P." The method of making manure, detailed in the pamphlet entitled as above, is by no means obsolete, although the book is somewhat old. On the contrary, the practice is very general, and thousands of farmers use some modification of the plan, if not the precise plan itself. The method is valuable and practicable on a small or a large scale, upon every farm in existence.

A Catch Crop of Turnips.—"J. G. Q.," Tioga, Pa., plowed four acres of stubble land after the grain was harvested last summer, brushed in 75 cents worth of flat turnip seeds, and in November pulled 1,310 bushels of turnips, some of them weighing 9 $\frac{3}{4}$ pounds each.

"Upland Game Birds and Water Fowl of the United States," by A. Pope, Jr., is the title of a remarkable work now in course of publication by Scribner, Armstrong & Co., N. Y. The work is to be published in ten parts, each part at \$2.50, giving two plates 22 x 28 inches, after water-color sketches from life, by Mr. Pope, with descriptive text from the best authorities. We style this as a remarkable work, and it is so in two respects: In the first place it manifests on the part of the publishers a confidence that the public will sustain a really good thing, and secondly, it is remarkable as showing the great perfection to which color printing has reached in this country. The plates are perfect reproductions of water-color drawings, presenting all the breadth and freedom of the originals—indeed there is nothing about them that suggests mechanical work. By all sportsmen and naturalists, the work will be highly esteemed. The plates are well worthy of frames, if one chooses to dispose of them in that manner, or they may be kept in a portfolio, or be bound, as one may prefer. Not only the plates, but the text and cover are marvels of elegance and perfection, and reflect great credit upon the house of Scribner, Armstrong & Co.

Special Fertilizers are now receiving much attention from farmers, and we are in a fair way to soon know how far we can profitably apply fertilizers, specially prepared to meet the particular requirements of various crops. The experiments given by Prof. Atwater on another page, show in a most striking manner the value of experiments in this direction. Those who wish to test the value of fertilizers prepared for special crops, after the method proposed by Ville, and others, will find much to interest them in a recent circular issued by the "Mapes Formula and Peruvian Guano Co.," 158 Front Street, N. Y. City. This circular shows a great amount of pains-taking labor, and gives the requirements as to nitrogen, phosphoric acid, and potash, of each of the leading farm crops, and in another table shows the prices at which these constituents may be supplied. There is no secrecy about these formulas, and one can purchase the special manures ready mixed, or, the constituents of each formula being given, he can procure them in any form he may prefer, and mix them himself.

Nebraska Land.—Attention is directed to the advertisement of lands for sale in Nebraska by a New York gentleman. The party is reliable.

Absorbent for Liquid Manure.—"E. C. N.," Elizabeth, N. J. The method of saving the liquid manure from the stables, and carrying it by drain to a cistern, is to be commended. A convenient manner of using the liquid is by mixing some absorbent material with it. Cut straw, leaves, road sweepings, sods, waste of different kinds, such as that from shoddy mills, or tanneries, and even earth from a garden or a field, all make excellent absorbents. Anything will answer, excepting such as would neutralize the valuable properties of the manure, or would add some injurious constituent to it.

Both Instruction and Amusement, in large amount, will surely be obtained from the *American Agriculturist* Microscopes during this year, by all readers, old and young, who will take a little pains to study how to use it. The "Doctor" has begun his lessons, (p.66,) which we advise all to consult and follow out.

Feeding Potatoes to Pigs.—"J. R. M." New Brunswick, Canada. The plan which we have found as good as any other, if not better, for feeding potatoes to pigs, is to provide a kettle, or boiler, to cook them in, and after the potatoes are roughly washed, if they have much earth adhering to them, they are mixed with corn ears, and the whole is boiled until the potatoes are softened to a mush. This, when cool, may then be fed as it is, or some barley, or oat meal, or bran, may be mixed with it when hot, and left to soak until cool enough to feed. We believe this plan saves one-fourth the value of the feed, which more than pays for the trouble.

Heavy Duroc Pigs.—We lately inspected a shipment of Duroc swine, whose weights were above the average of large pigs. The pig bred by W. M. Holmes, of Greenwich, N. Y., and illustrated in the *American Agriculturist* of December last, was among the number; he weighed 637 pounds, and was 20 months old. 28 carcasses shipped from New Jersey weighed 11,864 lbs.

Best Time to Cut Sprouts.—"H. P.," Georgetown, Texas. Sprouts from the roots of trees should be cut when in full leaf and vigor; the shock is then generally fatal to them.

Yield of Corn Fodder.—"R. M.," Pittsfield, Ohio. 2,000 lbs. of corn fodder for 10 bushels of corn is a fair average estimate. The average yield of corn is 30 to 40 bushels per acre, and the crop of stalks should amount to 3 to 4 tons per acre. Where the crop of corn is above the average, this estimate should be modified; as where 60 to 80 bushels per acre is produced the proportion of stalks would be probably not more than one ton to 15 or 20 bushels of corn.

Curing Hay in Pits.—"J. A.," Chehalis Co., W. T. In a moist climate where it is difficult to cure hay, the plan of preserving it by ensilage, as described in the *American Agriculturist* for June, 1875, may be adopted. This plan, if the directions given are properly carried out, will be successful. It is now practised by hundreds of large farmers in Germany and France, for the curing of green corn stalks, clover lucern, and leaves of beets, and is also in use for keeping brewer's grains in this country, by some prominent dairymen.

The N. J. State Horticultural Society will hold its next Annual Meeting in Geological Hall, at Rutgers College, New Brunswick, N. J., on Feb. 6th and 7th. An interesting programme for papers and discussions is offered. "All interested are invited."

Which is the Best Single Book for a Farmer?—While we think that every farmer may profitably invest in a library of moderate size, we are often called upon to answer the question proposed above. In giving a reply, we have to consider the wants of two classes. One, the average farmer, brought up to his occupation, but who wishes a work which he can consult upon matters in which he has had no experience. The other, the novice in farming, who would have some general guide which he can safely follow. We know of no work that will meet the wants of both these classes so well as the "*New American Farm Book*," originally by R. L. Allen, one of the founders of the *American Agriculturist*, and later revised, enlarged, and brought up to the times by his brother, Lewis F. Allen, well known as an authority on agricultural matters. This work covers the whole routine of ordinary farming. Of course if one makes a specialty of cattle, sheep, swine, or such crops as hops, broom-corn, etc., he will naturally procure works on these particular topics, but we know of no book that so thoroughly meets the wants of the general farmer as this. A glance at its contents shows that while all ordinary farming topics are treated in a satisfactory manner, sufficient is given upon special crops to give one an idea of their culture. Soils, their improvements, and their mechanical working, and manners of various kinds, and their uses, are discussed without introducing confusing scientific terms. Grasses and clover, being the groundwork of successful agriculture, have an important place; these are naturally followed by the various grains, root crops, and the different forage plants. The orchard, as an important part of every farm, has a chapter, while fences, hedges, roads, farm-buildings, timber-lands, cisterns—indeed, almost every thing belonging to a farm is treated plainly and in full. All the domestic animals, including poultry, with their management and their diseases, including their prod-

ucts, whether of the dairy, or their flesh when slaughtered, are treated of in a condensed, but most comprehensive manner. Not the least useful portion of the work is the tables, which give those things that one finds it so difficult to carry in mind, and equally difficult to find just when the information is needed—such as the amount of different farm seeds to sow to the acre; the number of trees or plants required for an acre at different distances apart; the comparative value of different foods; bulk of a ton of different articles; weight of a bushel of grains; contents of cisterns; value of fuel; composition of various agricultural products, etc. To those who, like the writer, do not dare to trust to memory for such data, a work of reference of this kind is of the greatest value. We cannot recollect having consulted this work on such matters without finding just the information we sought. It comes the nearest being an Encyclopædia of Agriculture of any work in the language. For the great variety of topics, the clearness of its teachings, and for its directness, we feel warranted in commending Allen's "*New American Farm Book*" as the best single work for the American farmer, and we are sure that it will prove to every one of a value far above its cost. It is a large 12mo. volume of over 500 pages, in clear type. It will be sent from this office, post-paid, for \$2.50.

Farmers Who Live Near Cities

or large towns, especially if these have a manufacturing population, can not afford to continue the old style of farming, and get only small crops of corn, potatoes, and hay to the acre. If the growth of towns and cities increases the farmer's taxes, it also enlarges their opportunities, by offering a market for certain crops, and at the same time affording a supply of manure. One used to the routine of the farm may not care to go into the details of market-gardening, where perishable crops must be marketed daily. But there is a medium between regular market-gardening, and the ordinary routine of farming, which is termed "*Market Farming*." This differs from market-gardening, in raising but a few of the less perishable crops, and from regular farming, in requiring higher culture, the sale of the crops, and the buying of manures. The farmer who lives within ten miles of a large manufacturing town makes a great mistake if he does not consult the wants of that place, and supply them. Take two crops for example—carrots and cabbages. In any large place where many horses are kept, there is a good market for carrots, and there is generally a ready sale for them, to be delivered direct from the field. Working people, such as factory operatives, know the nutritive value of cabbages, and these always meet with a ready sale in such places. Either of these crops is easily managed, and is sure to bring a larger profit than any regular farm crop. While market-gardening has been over-done in the vicinity of some large cities, there are many smaller places where it may be profitably undertaken, to supply the home market, and farmers' sons, instead of looking for work in the cities, had better buy Peter Henderson's "*Gardening for Profit*," and go to work at supplying the wants of the nearest towns. To those who would raise some of the less perishable crops, like those we have mentioned, we also commend P. T. Quinn's "*Money in the Garden*," and Frank Brill's "*Farm Gardening and Seed Growing*." The first two are sent post-paid from this office for \$1.50 each, and the last named for \$1.00. Any farmer near a large town, can profitably invest in all three of these works. Though on similar subjects, each has its peculiar features, and is well worth the price to any cultivator of the crops on which it treats.

Basket Items continued on page 73.

Important Farm Experiments.

Most soils, after a few years cropping, begin to lose their fertility. This is because the crops have taken away more of certain of the ingredients of plant-food than the soil has been able to re-supply. Barn-yard manure, which contains all the elements of plant-food, is usually employed to restore the lost fertility. But there is not half enough manure produced to give the renewed or increased fertility needed for the greatest profit, except on farms where a good deal of live stock is kept. Other fertilizers are needed for the most profitable farming. What shall they be? Farmers have been groping in the dark, trying guano, phosphates, bone, poudrettes, and what not, without knowing either what their soils and crops needed, or what the fertilizers supplied. And it is a fact that a very large part of the cost of all such applications has been wasted—an immense sum, certainly millions of dollars in the aggregate,—because many of these fertilizers have proved, if not really worthless, at

least not the thing needed—and others, while supplying the needed elements for the soil or crop, have furnished, at much cost, a large amount of material, valuable in its place, but not needed by the particular soil to which they were applied. Prof. Atwater, in his articles published in the *American Agriculturist*, during three years past, has been urging farmers, each for himself and on his own particular soil, and before investing largely in commercial fertilizers, to address questions to their individual soils in the form of experiments on a small and inexpensive scale, but so carefully that the questions would be answered. There is no doubt that this is the best way. A few experiments, with fertilizers costing \$3 to \$10, much if not all of which will be returned in the crop, will do more to tell the farmer what his soil needs, than \$500 or \$1,000 spent in analysis of the soil.—Such experiments have been recommended over and over again, by the leading agricultural chemists in Europe and America, and have been carried out by practical men with the greatest profit. They are rational, simple, easy, and cheap. To facilitate their introduction last season, samples of fertilizers of tested qualities, were sent out, at cost price, \$4.50—\$6.00 per set, from the Agricultural Experiment Station, at Middletown, Conn. Prof. Atwater gives some of the results elsewhere, (page 50.) For farmers to get samples of genuine fertilizers, with explanations of their composition and use, at such low cost, was something; to have the offer to test the fertilizers, and with them their soils, was more. Numerous reports from the men who have made the experiments, and are more than pleased with the results, attest their utility. These experiments ought to lead many other farmers to make similar ones. To aid them in so doing, there is talk of making arrangements to supply the subscribers of the *American Agriculturist*, who may wish them, samples of fertilizers for the coming season, as was done by the Connecticut Station last year; but no plan has yet been adopted, and may not be. If this is arranged for, it will be announced in our next paper.

American Cheese—Foreign Demand.

The broad pastures of our vast country are rapidly becoming feeders of Europe. The year just past has witnessed an increase of several hundred per cent in the export of fresh beef and mutton, mainly produced on the grass-growing and corn-producing Western prairie lands; and it only requires the general introduction of Short-horn blood among Western cattle to extend this export of fresh beef in the carcass, and of live beef cattle, to an immense amount. As fresh meat can now be taken from the Atlantic seaboard, and laid down in good condition in the chief seaports of Western Europe at small cost, we only need to produce good beef, to be able to compete successfully in the meat markets of the Western portions of the Old World.

But the South and the far West are not alone yielding exportable products. Large quantities of Cheese to meet a foreign demand are produced in the Middle States, as well as in several of the Western States. The following figures, from the U. S. Bureau of Statistics, shows a wonderful increase in the

EXPORT OF CHEESE TO FOREIGN COUNTRIES.

1860.....	15,515,739 lbs.	1869.....	39,960,367 lbs.

Bee Notes for February.

BY L. C. ROOT, MOHAWK, N. Y.

If all the proper requirements may be observed without disturbing bees during this month, it will be desirable. I found, by a quiet examination in my bee cellar a few days ago, that mice had found their way into the place, and were disturbing the bees by making their nests in the cotton quilts directly over the clusters of bees, where they found it very warm and comfortable. This may be agreeable to the mouse, but is not conducive to the quiet desirable for the bees. The mice may be easily caught by baiting an ordinary trap with cheese.... For hives wintered out of doors, follow directions given last month.

I propose to give, during the present winter, the respective amounts of honey consumed by four hives of bees each month. I have left one swarm on its summer stand, to show the difference in the amount required when bees are wintered out of doors, or when properly wintered in a well-arranged in-door repository. During the month of December, three swarms in the cellar consumed honey as follows:—No. 1, $\frac{1}{2}$ lb.; No. 2, $\frac{3}{4}$ lb.; No. 3, $1\frac{1}{2}$ lbs. No

3 is a very heavy hive, and in order to test the desirability of having swarms numerous in bees, I united four swarms before placing them in winter quarters. It should be borne in mind, by those who note these results during winter and spring, that this swarm commences the winter with four times as many bees as each of the other three. No 4, which is the live out of doors, consumed $4\frac{1}{4}$ lbs. No. 1, and No. 4, are both Italian swarms, and are, as far as I can determine, in nearly every way about equal. Yet the latter, being exposed to out of door changes of temperature, consumes $4\frac{1}{4}$ lbs., while the former takes but $\frac{1}{2}$ lb. This should be a point of interest to advocates of out-door wintering.

Review of the Live Stock Market for 1877.

The history of the live stock market for the past year has been an eventful one. The first six months of the year witnessed a slow but steady trade without serious fluctuation in prices. Then came the great strikes on the railroads which seriously interfered with business. For two weeks trade was practically dead, only a few poor local supplies furnishing stock for the butchers. Prices, however, only advanced to 14c. per lb. which was the highest point reached. From this time, onwards the business has been dull in the extreme and dealers and wholesale butchers, including those operating in the foreign shipments, lost heavily. Many failures occurred and business has been much depressed. The monthly sales of beeves for the year have been as follows:

Month.	Number Sold.	Prices.
January,.....	46,045.....	8c. @ 13c. per lb.
February,.....	36,036.....	7c. @ 13c. "
March,.....	37,542.....	7c. @ 12c. "
April,.....	40,639.....	7c. @ 12c. "
May,.....	52,877.....	8c. @ 12c. "
June,.....	39,241.....	8c. @ 13c. "
July,.....	45,776.....	7c. @ 13c. "
August,.....	38,487.....	7c. @ 14c. "
September,.....	30,824.....	7c. @ 13c. "
October,.....	50,387.....	6c. @ 13c. "
November,.....	36,379.....	7c. @ 12c. "
December,.....	35,901.....	6c. @ 13c. "
Total,.....	489,133	
Weekly Average,.....	9,406	

The sales of stock other than beeves have been:

Total.	Weekly Average	Range of Prices.
Cows,.....2,654 head..	51.....	\$22 @ \$30 per head.
Calves, 202,754 " ..	1,976	Calves, 7c. @ 9c. per lb.
Sheep & Lambs, 1,163,339 " ..	22,311	Sheep, 4c. @ 10c. "
Lambs,.....	5c.	Lambs, 5c. @ 13c. "
Swine, 1,144,195 " ..	12,003	Live, 4c. @ 7c. "
		Dressed, 5c. @ 8c. "

The foreign shipments of meats and live beeves and sheep, increased largely up to the fall months when the failure of several of the large operators showed the truth of what we have frequently stated as our opinion, viz: that the export business can never become anything more than a spasmodic affair, flourishing when prices are low and stocks heavy here, and when stocks are light and prices high on the other side. The expenses and risks are too great, and the profits, when any are made, are too small to sustain a steady trade. It may answer as a safety valve to relieve pressure here, but as soon as the pressure is relieved the movement must cease. We may build up a business in the course of years, but not until beeves bear a lower price here than we hope to see.

Instructive Notes about Switzerland.—How few have any very definite idea of our little Sister Republic in the Old World. Here are a few items for the readers of the *American Agriculturist*, which Mr. Judd has boiled down from his travelling Note Book.—Switzerland is a northern country, though it does not look so on the map; it is on a line east of Lake Superior, or Quebec, (lat. 46 to 48°). It is a high country, very little of its surface being less than 1,500 feet above the sea level. Many of its mountains are over a mile (5,280 feet) high; 38 of them over 6,400 feet; 29 are over 10,000 feet high, that is 2 miles and more; 8 are 13,075 to 15,150 feet high.—Switzerland's greatest length is 210 miles; greatest breadth, 140 miles; total area, 15,747 square miles, or one-third as large as New York State, or about twice as large as New Jersey or Massachusetts. Its people numbered in 1870 2,669,247, or about the same as Ohio, or in Illinois. Of these, about seven-tenths speak German; over two-tenths French, the rest speak Italian. They live in 92 cities and towns, 63 hamlets, and 6,800 villages. Over 350,000 children are taught in nearly 6,000 public schools. There are about 200,000 fighting men, viz.: 85,000 belonging to the field army; 50,000 reserves; 65,000 militia. The public revenue and expense is only about $\frac{1}{4}$ million dollars, or one-sixth as much as that of the City of New York alone. Its valleys and hill-sides are largely in pasture lands, supporting 993,000 horned cattle, 100,000 horses, 447,000 sheep, 375,000 goats, and 304,000 swine.—The Government is somewhat like our own: The NATIONAL COUNCIL, cor-

responding to our House of Representatives, contains 135 members, about one for every 20,000 inhabitants, elected by the people once in three years. The COUNCIL OF STATES, corresponding to our U. S. Senate, contains two members for each Canton. These two bodies together are called the "Federal Assembly," corresponding to the United States Congress, which is made up of our Senate and House of Representatives. The NATIONAL COUNCIL elects a President and Vice President at every regular and every extraordinary session, who are the chief officers of Switzerland during their term of office. The President can not be re-elected at two consecutive sessions of the National Council. The National Council, and Council of State, in joint session, elect, once in 3 years, 7 Executive Officers of the General Government, corresponding to our Secretaries of State, Treasury, War, Navy, etc. These, acting together, are called the FEDERAL COUNCIL.—The 22 Cantons and 6 Half Cantons of Switzerland, corresponding on a smaller scale, to our States, have their local governments, making local laws, etc., similar to our State Legislatures.

Science Applied to Farming.—XXXVIII.

Scientific Experimenting by Practical Farmers—Testing the Needs of Soils by Trials with Fertilizers.

As explained in the article of this series for April, 1877, there were sent out from the Experiment Station here, last spring, to farmers in Connecticut and other States, nearly 50 sets of fertilizers, with explanations and directions for experiments. With them were blanks on which those who might be willing to take the needed trouble in measuring plots and crops and noting observations and results, were requested to make out reports, and return them to me. To tell the truth, I did not expect many reports. Much to my surprise and gratification, nearly twenty have sent more or less detailed accounts of their experiments. All are interesting and instructive—some particularly so. As an application of science to farming by practical men, who get their living from the labor of their brains and hands upon their farms, and who have found in them a means of testing the needs of their soils, and the ways of supplying them, I am sure these results will be widely welcomed.

The principle upon which these experiments are based is, in brief, this:—The chief office of fertilizers is to supply the plant food that our crops need, and which the soils fail to furnish. It is not good economy to pay high prices for materials which the soil may yield in abundance, but it is good economy to supply the lacking ones in the cheapest way. The most important ingredients of our common commercial fertilizers, are *Nitrogen*, *Phosphoric acid*, and *Potash*, because of both their scarcity in the soil and their high cost. It is in supplying these that guano, phosphates, bone manures, potash salts, and most other commercial fertilizers are chiefly useful. To test the needs of the different soils with reference to these substances, was the special object of the experiments, though the action of different fertilizing materials with different crops was also to be tested. The table below gives the compositions and costs of principal materials used.

Experimental Fertilizers.

Number of Bag.	FERTILIZER USED.				FURNISHING VALUABLE INGREDIENTS.			
	KIND.	lbs. per Acre.	At price of 3 ton.	Cost per Acre.	KIND.*	Assumed per cent.	lbs. per Acre.	Cost per Acre.
I.	Dried Blood.....	320	\$40.00	\$6.40	Nitrogen.....	10	32	\$6.40
II.	Superphosphate.....	330	\$35.00	\$5.60	Phosphoric Acid +.....	16	51	\$5.60
III.	Potash Salt, "Muriate.".....	330	\$45.00	\$7.20	Potash.....	50	160	\$7.20
IV.	Dried Blood.....	160	\$40.00	\$6.40	Nitrogen.....	5	16	\$3.20
	Superphosphate.....	160	\$37.50	\$6.00	Phosphoric Acid +.....	8	25	\$3.20
V.	Dried Blood.....	160	\$40.00	\$6.40	Nitrogen.....	3.3	10	\$1.87
	Superphosphate.....	160	\$37.50	\$6.00	Phosphoric Acid +.....	5.3	17	\$1.87
	"Muriate of Potash.".....	160	\$45.00	\$7.20	Potash.....	16.7	53	\$7.20

* From bone-black. Some of the best "ammoniated" superphosphates are made of bone-black superphosphate, and dried blood. † In soluble form. The prices above, for cash, are, if anything, too high for the present state of the market. The 50 per cent "muriate" of potash, for instance, has been sold extensively in this region for \$40.00 per ton, plus freight from New York.

Besides the articles in the table, a number of others, as Plaster, Nitrate of Soda, Ground Bones, and Peruvian Guano, were supplied to those who wished them. They were all of the best quality, as tested by analysis at our laboratory. Each one

was contained in a bag of 20 lbs., on which the name and composition were marked. The several small bags were packed in one large bag, and with them were sent printed explanations and directions for using. With other suggestions, was one that parallel trials be made with other fertilizers. I give some of the experiments herewith, reserving others, with recapitulation and conclusions, for a succeeding article. The reports are essentially as they came to me; a few changes in form being made for the convenience of the printer.

Experiment with Corn by Mr. D. H. Birdsey, Middlefield, Conn.

Soil: Upland, gravelly loam, with gravelly subsoil. *Previous treatment:* Had been in grass for three previous years. Yield of hay estimated at $\frac{1}{2}$ to $\frac{3}{4}$ ton per acre. Last manuring was (with oats) leached ashes; previous to this, barn manure and bone. *Size of each plot:* 10 square rods. *Amounts of Fertilizers:* Plots 1—5, 20 lbs. each; Plot 6, yard manure, 5 cords per acre, with hen manure and ashes in the hill. *Amount of Seed:* 5 quarts per acre. *Distance between hills:* 4 feet each way. *Planted* May 15. *Harvested* Oct. 26. *Yield* (corn in the ear, measured in bushel basket) as below.

No. of Plot.	1	2	3	4	5	6
KIND OF FERTILIZER.	Dried Blood.	Superphosphate.	Potash Salt.	Muriate.	Muriate.	Yard and Hen Manure and Ashes.
Important Fertilizing Ingredients.	Nitrogen.	Phosphoric Acid.	Potash.	Nitrogen.	Nitrogen.	Yard and Hen Manure and Ashes.
Yield, Corn in the Ear.	24 bu.	24 bu.	6 bu.	24 bu.	6 bu.	54 bu.

Mr. Birdsey says in his report that "on Plot 3, with potash-salt, 5, with dried blood, superphosphate, and potash-salt, and Plot 6, with yard and hen-manure and ashes, (which also furnished potash,) the crops looked well through the season; the stalks were strong, and large, the ears well-filled, and the grain good. On the others (without potash) the growth was very poor, the stalks small, weak, and yellow, and the ears poorly filled—mostly 'nubbins.'... The potash worked wonders wherever it was put." He adds that "on this land, bone formerly brought good crops; with rye, about all the land would hold. But of late years bone does very little good, and don't pay. The same is true of phosphates." This is only one of a considerable number of cases I have observed in this region in which lands where bone, phosphates, guano, and fish, supplying phosphoric acid and nitrogen, have nearly ceased to do good, and potash salts have proved very beneficial. We have had two bone mills in the vicinity for a good while. Fish-scrap is cheap, and our farmers have used a good deal of guano and phosphates. It would seem as though some of our fields had become relatively over-charged with nitrogen and phosphoric acid, and deficient in potash. It is noticeable in Mr. Birdsey's experiment that: (1) on the three plots which had no potash the crop failed; (2) on the three, where potash was applied, they were good; (3) the crop with potash alone (No. 3) was as good as those with potash and other ingredients together, (Nos.

5 and 6.) It certainly looks very much as though this soil had enough of other materials than potash for the present supply. Mr. Birdsey has since bought the 50 per cent muriate of potash at \$42 per ton, delivered here. At this rate, the dressing of

Experiment with Corn, by Mr. W. I. Bartholemew, Putnam, Conn.

Soil: Hill land, surface, dark loam, moist, with clayey sub-soil.—*Previous Manuring and Produce Per Acre:* 1874, No manure; hay, 1 ton. 1875, Barn-yard manure, 12 cart loads; corn, 35 bushels. 1876, No manure; oats, 40 bushels.—*Experimental Crop, 1877:* White Cap Corn.—*Size of Each Plot:* 10 square rods.—*Amounts of Fertilizers Per Acre:* Experiment Station fertilizers and superphosphates, 320 lbs.; unleached ashes, 32 bushels; leached ashes, 48 bushels; hog-manure, 16 cart-loads; hen-manure, 20 bushels; night soil, 32 bushels.—*Fertilizers applied in the hill.* The dried blood and potash salts were scattered over more than a foot square in each hill, and covered with fine earth before dropping the corn.—*Hills:* $3\frac{1}{2}$ feet apart each way; 4 kernels in each hill.—*Planted:* May 15.—*Harvested:* Oct. 10.—*Quality of Crop:* As stated in table, the corn grown by the use of hog-manure and, especially, night-soil, was much injured by mould. The husks and corn were, in some cases, completely rotted with it.—*Amount and Value of Yields:* "70 lbs. of the best yields make a bushel of shelled corn, which is reckoned [in table] at 70c. per bushel. The smaller yields were greener in the cob and corn, and are hardly worth the price affixed, but I concluded to give the exact yield in pounds, and have computed yield and value per acre from actual weight in each case. [Multiplying amount in each plot by 16.] No allowance is made for worth of fodder, which was, on the different numbers, very nearly in the same relative proportions as the corn.—*Cost of Fertilizers:* [Those from Experiment Station, per table above.] "The price of superphosphates depending upon distance from market, I have reckoned all at cost at R. R. Station. [In estimate of gain from use of fertilizer, the omitted value of stalks would more than pay for carting and applying.] "I have placed no prices upon the manures from the farm, as their cost is uncertain, but I am certain that the expense of carting the hog-manure to the field, and applying it, is equal to cost of phosphates in either instance."

his experiment, 320 lbs. per acre, would cost \$6.72. He calculates that the stable manure of No. 6 cost \$40 per acre, besides the ashes and bone. He says that on the strength of this experiment he has bought several tons of potash salts and I learn that several of his neighbors have followed his example. In respect to the potash salts doing so well alone, this experiment is exceptional. I should not wish to invest too heavily upon the strength of a single experiment, on one field, with one crop. That potash is most wanted in that soil, I have no doubt. But in the next field the case may be different. As Mr. Birdsey's is one of the simplest, Mr. Bartholemew's is one of the most extensive experiments reported:

In Mr. Bartholemew's experiment, the following points are noticeable:—(1.) In the four cases, Nos. 1, 3, 6, and 7, where phosphoric acid was not supplied, the crop failed. (2.) In every case where phosphoric acid was supplied, either alone, (i. e., as superphosphate with the lime and sulphuric acid incident thereto,) in No. 2, or with some, generally little, nitrogen, in Nos. 2, 5, 8, 9, 10, and 11, the crop was good. (3.) The amounts of phosphoric acid per acre in Nos. 2, 4, and 5, were 51, 25½, and 17 lbs., respectively; the yields, 182, 166, and 146 lbs. show a corresponding decrease. Comparisons of the amounts of phosphoric acid applied, and corn produced in the other cases, of which limited space excludes details, show a similar and singularly uniform ratio between the two. This parallelism between phosphoric acid and yield, runs through the plots with ashes which contained less of the acid, and brought less corn; and those with farm manures, which contained more, and brought more. (4.) The yield with potash-salt, and with dried blood alone, was less than on the one plot with no manure. (5.) While the crop responded uniformly to the phosphoric acid, it got no apparent benefit from the other ingredients of either the chemical fertilizers, the ashes, or the farm manure. (6.) As indicated by the money costs of fertilizers applied and corn produced, there was uniformly a gain of from \$10 to \$12.50 per acre from phosphoric acid alone or with a little nitrogen, a smaller gain in each case where phosphoric acid was supplied with other substances, and, in every case where it was omitted, a loss. What that soil needs most, is clearly phosphoric acid.

This report of Mr. Bartholemew's experiment with fertilizers, is one of the best I have seen from a private farmer in this country. If his farming is equal to his experiments, and there are many others in that region like him, it is easy to see why the Woodstock Farmer's Club, of which I hear he is a

member, and the farming thereabouts, stand in such excellent repute. W. O. ATWATER,
Wesleyan University, Middletown, Conn.

REQUISITES FOR AN ICE-HOUSE.—Ice may be kept under any circumstances, and in any kind of a house, if the following conditions are secured and maintained. The floor upon which the ice is packed, must be perfectly well drained, and closed against access of air. The ice must be in a sufficiently large body, at least 8 feet wide each way, and be stowed compactly, without air spaces between the blocks or layers. If spaces between the blocks can not be avoided, these should be closely filled with pounded ice. The ice should be cut and packed on a dry, cold day, when the blocks will freeze solidly together. There must be a perfectly air-tight, or non-conducting packing, around the ice, of at least one foot in thickness. Dry sawdust is the best material for packing; waste tan bark is nearly, if not quite as good. There must be ample ventilation above the ice, to carry off the dampness which will arise from the packing. The evaporation of the moisture from the upper packing by a brisk current of air, appreciably reduces the temperature. The most frequent causes of failure in keeping ice are, the entrance of air from beneath; the presence of water at the bottom which can not escape, imperfect packing, and too close confinement above.

THE N. Y. STATE DAIRYMEN'S ASSOCIATION, held its Annual Convention at Syracuse, on December 18th. The Hon. Harris Lewis, the President, remarked, in his address, that the past year's success could only be repeated in the coming season, by making every effort to supply all deficiencies in methods, practice, and appliances, and to bring a proper enthusiasm to bear upon the dairy business. He thought that those young men who left the farms to go to the cities, because farming was distasteful to them, did well, for if they staid on their farms the sheriff would surely sell them out in time. A love for one's business, he that what it may, is essential to success. The reading of several practical papers, and a visit to the salt works at Salina, occupied the two days of the Convention.

THE UTILITY OF DAIRY AND OTHER EXHIBITIONS.—Many farmers, dairymen, and others, engaged in different branches of agriculture, not to speak of various artisans and manufacturers, are

inclined to consider exhibitions of their products a useless and expensive trouble. This idea is a mistaken one, as the direct results of these exhibitions are very valuable, and their indirect influence, equally, if not more so. The public are made aware of the existence of many things heretofore unknown to them, and thus consumption is largely increased; the close comparison of the work of different producers, and the ambition engendered by this, tend greatly to an increased excellence in the products, and many new ideas are gained. There are other advantages besides these, but if these were all, they would be sufficient inducement to make these exhibitions desirable, not only to those most closely interested, but to the general public. As an illustration, may be cited the case of a dairy exhibition held annually at Frome, in England, where cheese to the yearly value of five millions of dollars is made. The result is, that since 1870, when the first show of cheese was made, an improvement in quality, estimated at 50 per cent, has been made, and the yearly returns to the district have increased a million dollars.

Tree Scraping and Tree Scrapers.

BY L. D. SNOOK, YATES CO., N. Y.

If orchards were properly cared for, there would be no need of tree-scrapers, but with this, as with pruning, it is a too frequent practice to allow the trees to get in as had a condition as possible, and then to have a serious time at pruning, scraping, and renovating generally. If our yearly advice, to give the trees each spring some alkaline wash, were regarded, there would be little use for the scraper. If one once puts the trunks of his trees in healthy condition, they look so much better, and really are so much more healthy and thrifty, that we are quite sure that he will not omit the slight yearly labor required to keep them in this condition. If one has a neglected orchard, he should not let this spring go by without an attempt to renovate it. Old trunks covered with loose scales of bark, and coated with lichens and mosses, should have in the first place a thorough scraping, and this should extend along the larger limbs so far as is necessary. After this scraping they should receive a strong alkaline wash. There is nothing, to our notion, so good for this purpose as good home-made soft-soap, made from ley (or potash) and grease. The boughten soft-soap is mainly a fraud, it being only cheap hand soap made into a sort of jelly with water. If good home-made soft-soap can be had—

The Cheese Factory.

The tendency of modern improvements is to lighten labor and increase its effectiveness. By the introduction of various kinds of machinery, men engaged in agriculture are enabled to do in one day as much as could be done in a week without them. What the mower, reaper, and thrashing machine have done for farmers, the cheese factory has done for their wives and daughters. Years ago the work of the farmer's wife was never done. The first to go to work in the early morning, she was the last to rest, late in the evening, and after taking her share in the milking and the care of the milk, the churning and cheese-making, with all the slopping, and washing of pans, pails, cans, tubs, churns, and cheese-presses, were added as additional duty to the already sufficient cares of the household. The invention of the factory system changed all this, and relieved the women

of the farm, not only from the care of the milk, but in a great measure from the milking as well. In the farmers' households there is now much more of comfort, leisure, and culture, than there was before all the labor-saving improvements were adopted, and where these are made the most of, there is more profit than formerly. There is more money passing through the dairy farmer's hands now than ever before, and the location of a cheese factory in a dairy district is, to be considered as a decided benefit. The market for cheese is only opened as yet, and before it can be fully occupied, the number of cheese factories may be greatly multiplied. The home demand for this form of food has never been cultivated, the foreign market having received all the attention. There has been no desire to consult differing tastes, and but one kind of cheese, and good, bad, and indifferent of the kind, has been manufactured. An exacting purchaser of cheese might travel over a considerable portion of a large city, without finding any choice beyond an ill-flavored, leathery product which goes by this name, unless he found, by mere accident, some foreign cheese, or some of American make put up in the form of the foreign article, and intended to compete with it. It is a question whether the makers or the consumers are most to blame in this. But it is rarely that a good thing goes a begging for purchasers; on the contrary, a supply of it at once creates a remunerative demand, and which rapidly enlarges as the commodity becomes known. If we had a plenty of cheese of different qualities and shapes, calculated to please the palates

and the eyes of purchasers, there is no doubt that our home market would soon increase so largely, that many new factories would be required to supply the demand, and that the prices obtained for the best product would be very profitable. The process of making factory cheese differs in

would be necessary in seeking a market. As the cheese factory is open but a portion of the season, this income therefore represents not much more than three-fourths of the product from each cow, and during the remainder of the time she adds to the amount of this income. As a rule, each dairy

cow may be made, by the help of the factory, to yield the income stated in cash, besides furnishing some butter for family use or sale during the winter, when the factories are closed, if proper arrangements are made for this. With all their manifest advantages, it is strange that there are not more factories in districts where cows could easily be kept, as well as that dairymen should be contented with cows of so poor an average quality as are common. The experience of the past year, however, during which market gardening has been a losing business, has turned the attention of many farmers to the keeping of cows and the production of milk, and it is reasonable to expect that several factories will be erected in the neighborhood of

the large cities where various articles of food, richly productive of milk, can be cheaply procured.

The cheese factory routine is very simple, and is reduced to a very thorough system in which everything is conducted by strict rule. The milk brought to the factory by the patrons is weighed in a large receiving can, (see fig. 1), and is then run through a strainer and a tin spout into the vats, where it is brought by steam heat to the proper temperature for adding the rennet. The different processes through which the milk passes before it finally appears in the finished shape in the curing room, are

referred to elsewhere. The last stage is by no means an unimportant one. The curing process needs to be managed with the greatest care. The curing house in which the cheese are kept to ripen, and await a purchaser, (shown in figure 2), is constructed so as to maintain an even temperature. The walls are double, and the space between them is filled with sawdust, or other non-conducting material. Steam pipes for heating the room in cool weather are fitted around the walls in many factories, and ample ventilation is provided for. The windows of the curing room are shaded with blinds, or what is preferable, should be made only upon the north side of the building. This room is generally situated above the "make-

Fig. 1.—CHEESE FACTORY.—RECEIVING AND WEIGHING THE MILK.

Fig. 2.—CHEESE FACTORY.—THE CURING ROOM.

milk, is greater than he could realize in any other way. An average of 2 cents per quart, or a gross sum of \$40 to \$50 for the season is the satisfactory and profitable income from each cow, when well managed; and this is paid in cash as the cheese may be marketed, without the loss of time that

room," but in some factories a separate building is provided, where the stock of cheese can be kept free from all the effects of dampness, changes of temperature, or the partly vitiated atmosphere from below; as the quality and value of the cheese depend upon the perfectness of the curing.

Among the Farmers.—No. 25.

BY ONE OF THEM.

I have heard from several sources the intimation that the hint that improvement in farm practice was indicated by the quantity of roots grown, as suggested in a recent letter, was quite correct, and that in every part of the country the great need of agriculture is

More Roots.

I have sometimes thought that the reason we did not cultivate more roots was because we have no regular place for them in the rotation to which time-honored custom subjects mowing land, when the grass grows thin, and we think it ought to be "taken up." We swing around the circle—corn, potatoes, oats, (or rye), seeding down at the same time; and then mow as long as we can; or we follow some other rotation, sowing a few turnips as a "catch crop," perhaps, where early potatoes have come off; and so getting a ton or two every year. This is not enough. When milch cows can not have grass, they ought to have, at least, half a bushel of roots a day. At that rate, each cow will eat half a ton a month, allowing about 10 per cent for loss. That quantity is none too much for dry stock which are being well wintered. Our farmers are well aware that the better cows are wintered, the surer and better are their returns when they come in. Yet roots make so much milk that I find where milk can not be sold, it makes so much work in winter with usually poor returns, that an abundance is objectionable, and so there is little inducement to grow roots. However, milk in winter is becoming desirable over almost the whole country. Intelligent farmers are studying the Guenon system which, if it have a real value, indicates which cows will hold out well with their milk, and which will not; and does this while they are mere calves.

Seeding Down to Grass With Roots.

I did not intend to convey the idea in the December number that seeding land down with turnips was a new discovery, for I have seen it practised and written about it before, but have never done it. I remember seeing on the Island of Jersey, a beautiful stand of grass and clover, so thick and strong in October that it looked like a spring seeding, and yet it had been sowed with turnips in July. The roots had been pulled from a good part of the field for feeding to the cows in the byres, and the animals were then being tethered upon the grass. On those parts of the field where the roots were growing in spots, they were almost hidden by the strong rye grass. Yet the yield seemed to me very large. It is sometimes risky to apply such foreign practice in this country, our climate is so different. The summers are hot and dry, and our times of sowing and harvesting differ also. Nevertheless, this is a case in which it would seem we might transplant the custom with success. In fact, I hear of so many cases of successful practice, that it may be confidently recommended.

A letter from Judge Fullerton, of the New York Bar and Bench, but whose large farm is in the vicinity of Washington, says that he has practised seeding down with roots with entire success.

I went over my neighbor Farlee's farm, at Cresskill, the other day, and saw several things worth making a note of. One was the excellent stand of grass where Swedes had been raised. It is new practice with him, but he likes it very much. The roots are sown in drills, but the culture is flat, and the land, after the roots are pulled, is so level that a mowing machine might be used on the field. The grass was sown in August, and makes as much show on the ground as late sown winter grain.

Mr. Crozier tells me that there is no difficulty about sowing grain, or grass, with mangels or sugar-beets, with as good success as with turnips, even though the ground be ridged and manured in the ridges. The culture tends so to flatten the ridges, that by the first of August, which is as early as grass or grain ought to be sowed, or it may be a little earlier, in case the growth of the roots is such that the crop must be "laid by," it is for all useful ends level. The seed will start well under the

shade of the leaves, and, as a rule, these begin to wither at the base, sufficiently to give light and air to the young grass plants, while they are sheltered from too great heat. Sometimes the shade is too much for the good of the grain or grass, but as the season advances it catches up.

The Kind of Roots to Raise.

A good deal depends upon distance from market. If farmers are near as Bergen County and Long Island farmers, it is worth while to put in root crops that may either be sold or fed. This might lead to settling down in favor of Swedish turnips, carrots, and parsnips, for the principal crops.

The Best Swede is undoubtedly the "Shamrock." It comes to this country from England, and its name ought to make it a favorite with farmers and gardeners from the Emerald Isle. Having the merit of growing very quickly, and attaining a large size, while it is smooth and fair in outline, with very little neck, it is adapted to both marketing and feeding, to an unusual degree. Sowed late, it produces the fairest market crops; sowed early, few, if any, varieties exceed it in size, and if it be in soil adapted to its rapid growth, its flavor is sweet, and it is unusually free from pithiness and woody fibres. Among the several slightly-varying kinds which pass under the name of the "Improved American Rutabaga," some are excellent, and perhaps equal to the "Shamrock," but the name does not indicate, by any means, so constant qualities.

The Best Mangel.—In regard to this, I find opinions vary a good deal. The "Long-Red" is the old favorite, and it may be that a greater weight of fodder may be produced to the acre of the improved varieties of this than of other kinds, but the Globe Mangels are growing greatly in favor, especially those of the richest yellow color of the flesh. This color being more or less imparted to the milk and butter, it becomes an object to cultivate those which possess it. The old "Yellow Globe" has been improved by several parties, and of the yellow kinds which are new, and have been well tested, "Warden's Orange Globe," and the "New Kinver," are decidedly the favorites. The latter is one which some of our best growers extol highly, equally for yield, for smoothness, and for color. The varieties claiming special favor originating from the Long-Red, and much like it, only growing larger, and smoother, and with less neck, are "Carter's Mammoth," and the "Norbiton Giant." The amount of leaf which some of the improved sorts have, seems absurdly small compared with the great bulk of the roots, yet this very peculiarity would recommend them in case one wanted to sow grass or grain with the crop.

The Best Carrot, both for feeding and for general marketing, is, without question, the "Half-long Orange," called also "Half-long Red" by some. This is precisely the color of the "Long Orange" carrot, but is much shorter, having quite the character of a direct cross between the "Early Horn" and the "Long Orange." This medium-sized carrot is an enormous cropper, of a smooth, beautiful shape and color, carrying its thickness well to the tip, and a very attractive market sort as well as an excellent table variety. In fact, it seems to leave little improvement possible, or at least probable. It should be borne in mind that imported seed is not nearly so good as the best American.

The Best Parsnip is probably the "Long, Smooth White,"—best, because it yields large crops, and is smooth and long. The several varieties of long parsnips are much alike, and there is little choice between them.

Corn Fodder—A Great Crop.

Once or twice during the summer I passed a fine field of corn, sowed in drills, not far from Mr. Farlee's, and had a suspicion that he had been hiring a piece of ground for the purpose; but why he should take an old worn-out field, which had lain idle long enough to have cedar trees four inches in diameter at the root, growing upon a good part of it, I did not see. As I was saying, I went over his farm a few days ago. My errand was to see his fine herd of Jerseys, and well worth the visit as they were, that field of corn made quite as strong

an impression. The land, it seems, has been held for speculative purposes, and is owned by a relative, so Mr. Farlee obtained the use of it rent free if he would grub out the cedars, and put it in good cultivation. This, most people would think, was paying dearly for the use of the land; but it lay convenient, and the sequel shows his plan was a good one. The cedars were grubbed out, the land plowed, furrowed out, liberally dressed with hen-manure compost in the drills, and sowed with corn for fodder. It was kept clean, and the corn made an enormous growth. The season was very favorable. Mr. Farlee cuts up his corn fodder, and after it wilts upon the ground for a day or two, if the weather be favorable, otherwise at once, it is set up in big stooks, and securely bound. These stooks are twice as large as ordinary corn-stooks—they are constructed around a stooking-horse, and the corn fodder is left in them all winter, or until consumed. When brought into the barn, those are selected which show signs of weakness—of course, first any which may have blown over, though if well set up this does not occur very often. The outer leaves and stalks are of course considerably weathered, but within the color is green and fresh, and cattle eat almost the whole. The value of this single crop will pay for the clearing, and all the labor and manure required to produce it, and leave a handsome balance over.

I have never seen corn fodder better secured, nor in better shape for standing well through the winter. A small portion only of it will be damaged by contact with the soil, and the labor of harvesting this crop, which is such a bug-bear as to prevent many farmers from undertaking to raise it, or as much of it as they would like, is thus reduced to a minimum—certainly less than securing the hay crop which would be produced on the same land.

Writing about raising fodder corn reminds me of the importance of

Cutting Corn Fodder

when it is fed out. My cows are getting little else now in the way of dry fodder. It is cut by hand, in inch hits, moistened with scalding water, sprinkled with rye bran and a little corn and oat meal, covered up with a rubber cloth, and left to soak and swell from morning to evening, and evening to morning. The result is, it is eaten up very clean, a double handful of butts a day being all that the most fastidious cow rejects. In cutting up a bundle of exceedingly large, coarse stalks, the cuts just at the but are made four or five inches long, on purpose to have them in shape to go into the manure. The cutting box which I use, is on the principle of the old-fashioned "cutting box and hay-knife," but much stronger, heavier, wider in the throat, or narrow part of the box, and easier to work. It is known as Clark's hay-cutter, and costs \$7 or \$8, I believe—at any rate, mine did. It may be regulated to cut about one inch to an inch and a half long, but I prefer to leave it so that the length of the cut may be optional with the cutter.

When large quantities of stalks, straw, or hay, are to be cut, of course no such "one-horse" apparatus as mine is admissible. A power cutter is needed, and is by far the most economical. These may be operated by horse, bull, or steam power, and there are several really first-class machines.

The English name for implements for this purpose is "Chaff Cutters." That is, machines for converting hay, straw, etc., into *chaff*, and certainly finely-cut hay, or even corn stalks, is very like what we call chaff—that is, oat or wheat chaff. I wish our manufacturers would adopt this name—it is surely a good one; and we have *cutters* enough without this application of the word.

Hay-Knives or Stack-Cutters.

I have never had much experience with hay-knives, and yet have used several of different patterns. Lately, however, I have been using one of the "Weymouth Patent Knives," and an admirable one it is. It is made sword-shaped, with a zig-zag edge, the front edge of the zig-zag only being sharpened. It is certainly not more than half the labor to cut through the hay with this knife, that it is with the ordinary ones. The benefit of cutting

from the side of a mow, or stack, is so great that I wonder at myself that I have ever been contented to pitch off hay from the top of the mow, unless indeed I wanted to use some particular kind of hay, the location of which was accessible there. The obvious advantage of the use of the knife is that hay gotten in early, with the sweet fragrance of vernal grass, and clover, may thus be mingled with that of later growth, wiry, perhaps, and lacking in flavor, though not in nutrition, and sometimes even in that, and this with the succulent aftermath perhaps, all together being highly relishable. Its use admits of sorting horse from cow hay, or throwing out any that may have heated.

Talks on Farm Crops.—No. 12.

By the Author of "Walks and Talks on the Farm,"
"Harris on the Pig," etc.

"I have lately read several articles in the papers," said Charley, "recommending rye as a green manure for potatoes."

"This crop," said I, "has certainly several things to recommend it for this purpose. It grows late in autumn, and early in spring, and thrives best on land most likely to be benefitted by plowing under a quantity of green vegetable matter."

"For our own use," said the Deacon, "we select potatoes grown on light, dry, sandy soil. They are cleaner and smoother than if grown on heavier soils, and are supposed to be of better quality than on low, rich, alluvial, or mucky land."

"On my farm," said I, "the old men, who worked on it before it was underdrained, frequently remarked: 'The east side of this field, or the north end of that one, or the west side of such a lot, is good for potatoes'—and in every case they select dry, sandy, rolling land. I have no doubt as to their general correctness. Still, since underdraining, we often get far larger crops on the rich, dark soil in the valleys. Last year we had a great crop of 'Early Vermont' potatoes on the lower portion of a field where, before draining, nothing would grow except coarse grass and rushes. The soil is a black, mucky sand. On this the crop was not only unusually luxuriant, and the yield large, but the potatoes were of remarkable excellence."

Facts of this kind lead us to suppose that potatoes like a loose soil, rich in decomposed carbonaceous matter. And, this being granted, it seems not unreasonable to conclude that it is a good thing to plow under some green crop, which will furnish a considerable quantity of carbonaceous matter. Rye is recommended for this purpose.

"And in addition to the carbonaceous matter," said Charley, "it is claimed that when we plow under a crop of rye in the spring, we turn under a large quantity of water which keeps the ground moist, and enables the crop to withstand drouth."

"These arguments," said I, "are very plausible, but will scarcely bear a critical examination. In the first place, a crop of rye which, if cut and cured, would afford two tons of hay or straw, would not, in its greenest and most succulent condition, contain over 11 tons of water. The crop plowed under adds to the soil less than would be furnished by one-tenth of an inch of rain. Furthermore, the growing crop of rye would suck up out of the soil, and evaporate into the atmosphere, far more water, during a few days previous to its being plowed under, than the crop contains. Lawes & Gilbert determined, by actual experiment, that on June 27th and 28th, 1870, an acre of fallow land, 4½ ft. deep, contained 2,875 tons of water, while an acre adjoining, in barley, contained, to the same depth, only 1,951 tons of water. In other words, the roots of the barley had sucked up out of the soil, 924 gross tons of water per acre, equal to 1,034 of our tons. To grow a crop of rye, and turn it under for its water, is absurd. It would be much more reasonable to suppose that the good effect of the rye was due to its evaporating such a large quantity of water from the soil, and so making it drier."

"There may be something in that," said the Doctor. "We are too much inclined to look on all our agricultural practices in reference to their action on the supply of plant-food. There are other

things equally important, and draining is one of them. We drain to get rid of the water that the soil will not hold. If it holds 25 per cent of water, and it contains 30 percent, then we drain to remove this 5 tons of water out of every 100 tons of soil.

"Mr. Lawes found that the plot of land in his experimental wheat field, which has received no manure for many years, contained to the depth of 9 inches less than 23½ per cent of water, while the plot adjoining, which had received 14 tons of barn yard manure every year for 23 years, contained nearly 34½ per cent of water. In other words, the 9 inches of surface soil of the 'no manure plot,' contained 352 tons of water per acre, while the plot adjoining, only a few feet distant, which had been heavily manured for many years, contained 517 tons of water per acre. The land is thoroughly underdrained, and one plot, so far as surplus water is concerned, was probably just as wet and just as dry as the other. The examination was made in January, and we may presume that the no manure plot, at any rate, was saturated with water. It contained all the water it would hold."

"This is an interesting fact," said the Deacon, "and explains why our soils, when new and full of organic matter, did not need draining so much as they do after being cultivated and cropped for 30 or 40 years without manure. It explains, also, why we suffer more from drouths than formerly. There is far less moisture in the soil than there was when the country was new, and when the soil was full of what you call 'natural manure.' But I do not see what all this has to do with plowing under a crop of rye for potatoes."

"Simply this:" said I, "It is difficult to explain why the rye should do so much good as is claimed. It seems absurd to attribute this to the water in the rye. And it has not been proved that the carbonaceous matter, which the rye gets from the atmosphere, is specially needed by the potato crop."

Here is an experiment made in 1871, on a sharp, gravelly, overcropped soil, in poor condition:

Plot 1—without manure, produced.....	70 bu. per acre.
" 2—with superphosphate and ammonia.....	186 "
" 3—with superphosphate, ammonia, and potash.....	304 "
" 4—with 20 tons farm yard manure.....	197 "

Plot 3—with ammonia, phosphates, and potash, and no carbonaceous matter, produced more potatoes than Plot 4, with farm yard manure, which, in addition to the ammonia, phosphates, and potash, contained a large amount of carbonaceous matter. And we should expect a "sharp, gravelly soil," to be unusually poor in carbonaceous matter.

Now it may be taken for granted that the rye does not get anything from the atmosphere except carbonic acid. The nitrogen and mineral matter it gets from the soil. If you grow and plow under a crop of rye, you add nothing to the soil except carbonaceous matter. And, so far as I can see, the good effect of the rye must be due to some of the following causes:—1. The roots of the rye find a quantity of soluble plant-food in the soil. They gather it up, and when the rye is plowed under, this plant-food is left in a more compact or concentrated form. The roots of the potatoes can perhaps use it to better advantage than if it was distributed through the soil.—2. The rye, by evaporating water, may make the subsoil drier during the winter and spring months, and to that extent have the same beneficial effect as underdraining.—3. The rye may get considerable carbonaceous matter from the rain and atmosphere, and this, when the crop is plowed under, decomposes, and renders the soil more retentive of moisture.—4. The rye may keep the soil loose and render its mechanical condition more favorable for the potatoes.

It cannot be doubted, from the facts which have been published, that plowing under a crop of rye sometimes proves of great benefit to the following crop of potatoes. But I have an idea that much will depend on the character of the soil and on the season. The practice may in some seasons be a good one on some soils and not on others. If I had a crop of rye sown for plowing under as a green manure for potatoes, I would plow it under; but if I had not, I should not despair of being able to raise just as good a crop by other means.

If the growth of the rye makes the land drier,

the same effect can be obtained by underdraining—or we can plant on land that does not need draining. If the rye makes the land loose and mellow, good tillage will do the same thing. If the rye concentrates the nitrogenous and mineral plant-food, we can apply this same plant-food in artificial manures. If, in addition to this, it furnishes carbonaceous matter, farm-yard manure will do the same thing. But after we have done all that we can do, we shall still be very much dependent on the season. And it will be a good plan to plant our potatoes at different times.

Three years ago (1875) we had a remarkably favorable season for potatoes. When the land was in fair condition, we had a good crop, whether we planted early or late, in hills or in drills.

In 1876 we had a fair crop on very rich, well drained, warm, loose, sandy loam, when we planted early varieties, early, kept the soil clean and fought the bugs. But late varieties, planted early or late, or early varieties planted late, were, on my farm at least, and also on the Deacon's, a failure.

Last year (1877) late planting of early or medium varieties gave fully as good a crop as early planting. In 1876 we had a moist, growing spring, followed by a great drouth in July and August. And the drouth and the bugs left the late planted potatoes no chance to grow. The early varieties, when planted early, had got a good growth before the drouth seriously injured them.

Last year we had a severe drouth early in the season, and abundant rains in July, August, and September. Hence the late planted potatoes, where the soil was favorable, grew rapidly, and produced a fair crop. I had several acres of "Late Rose" potatoes, planted on June 16th and 17th, that made a vigorous growth, and gave a good crop. The land was a clover sod in fair condition, turned over immediately before planting, and no manure used.

If the season is favorable, and the land is clean and mellow, a late planted crop of potatoes will have a ranker and more luxuriant growth, than a crop planted earlier in the season. My early planted potatoes, last year, were liberally manured, but the vines were never as dark colored and vigorous as those planted late without manure.

Where "Early Rose" or "Early Vermont" potatoes are grown for an early crop, it is necessary to plant early and manure liberally. We have to "force" them—not by artificial heat, but by extra manuring. An unnaturally early crop is a costly crop, and is only profitable where we can get an extra price. Where "Early Rose" potatoes are raised, as they are to a considerable extent in this section, for sale as a common farm crop in the fall, it is very doubtful whether we can afford to plant them very early. They require much richer land, or more manure, than they do when planted later.

"That is all true, theoretically," said the Doctor, "but as a matter of actual practice, I suppose our friend, the Deacon, will tell us that it depends a good deal on the season; your suggestion to plant part of the crop early, with liberal manuring, and part late, with less manure, is safe and sound."

"Well," said the Deacon, "I had about concluded that we should have to plant early kinds of potatoes, and plant them early, so that they would get out of harm's way, or the bug's way, before harvest, but I am not sure that late planting of early potatoes will not sometimes give better results. It will depend on the season. The main crop of potatoes will be raised, not from an early variety, nor yet from a late variety, but from a half early or medium variety like the 'Late Rose,' and it will be planted just before or just after corn planting."

I presume the Deacon is right. But if I had very rich land in prime condition, and wanted a big crop of autumn or winter potatoes, I would plant the "Late Rose" as early as the condition of the land and other spring work would admit—say as soon as we had sown our barley and oats.

"But suppose," said the Deacon, "you had poor land?"—"Even in that case," said I, "early planting gives us the best chance. I would plant early, in hills 3 feet apart, and use large sets with only a few eyes in a set, and only one set in a hill."

"I have known just as good crops," said the Doctor, "raised from small seed as from large."

"On that point," said I, "much depends on circumstances. If I got seed from a distance; if the land was rich, warm, and mellow, and everything favorable, and if we planted early, I would prefer small or medium sized potatoes, rather than large—not that I should expect a larger crop, but because the small seed would plant twice as much land, and thus reduce the cost of seed one-half. But if the land was in poor condition, and we were obliged to plant late, I should prefer the larger seed."

Making Wheels by Machinery.

The lightness, elegance, and surprising strength of American carriage wheels are well known, not only everywhere in this country, but are considered remarkable in Europe. American carriages are becoming fashionable in England, now that their lightness has been found consistent with actually greater strength than is possessed by the heavy, lumbering English vehicles. Our carriages, wagons, and wheeled vehicles generally, owe much of their beauty and usefulness to the excellent structure of the wheels, and this is principally due to the excellence of the machinery by which all the parts of the wheels are made and fitted together. Formerly it was a long and tedious labor to make a wheel, and when it was made, the joints were ill-fitted and soon worked loose. When a wheel gives out, the carriage is useless, and it is therefore of the greatest importance that the wheels of all our vehicles, subjected to very hard usage upon our generally miserable roads, should be made in the best manner and fitted with exactness. It is only by the use of machinery that joints can be made to fit perfectly close, and that every mortise and tenon of this kind in a wheel should be precisely alike. Since machinery has come into general use, and there have been such extensive wagon and carriage manufacturing as those of the Milburn and the South Bend works in operation, farm and road wagons and carriages of all sorts have been greatly cheapened and improved. The work about a wagon or carriage requiring the greatest skill, is in the wheels. If the joints are not well made, the

more severe test of the perfection of a wheel can be exacted than that of the arid plains of the West;

Fig. 3.—HOLLOW AUGER.

and machine made wheels have stood this test without failure. The machinery used in making wheels is very varied. The hubs are turned in lathes and mortised by mortising machines; the felloes are sawed by band-saws, which cut several pieces at one operation, and the spokes are turned in a lathe and tenoned by a tenoning machine. All this is simple work, however, and could be done very well by an expert mechanic by hand. But to bore out the hub perfectly true, with a tapering hole if required, and at right angles with the plane of the wheel, is hardly possible to be done by hand in every case, even by the most skillful workman. This, however, is done by the auger shown at figure 1, which is held at right angles to the rim of the

Fig. 4.—MAKING TENONS.

wheel by the clamps shown at figure 2. This ensures the proper boring of the hub and the true running of the wheel upon the axle. The tenons of the spokes are cut with the hollow auger shown at figure 3. This is mounted upon a frame, upon which the hub is also mounted, as shown at figure 4, and thus every tenon is made to bear an exact and proper relation to the hub and the axle and with each other. The felloes are bored in the manner shown at figure 5, and each hole being of precisely the same size and in the same direction, is made to fit any one of the tenons of the spokes. This ensures the easy but perfectly accurate fitting of these parts, and the consequent strength and durability of the wheel, although it may be of such exceeding lightness as is seen in one of the road wagons to which the fastest roadsters are hitched. The machinery here illustrated is made by the Silver & Deming Manufacturing Co., Salem, Ohio.

Comparative Value of Pedigree and Non-Recorded Jerseys.

BY THOMAS FITCH, NEW LONDON, CONN.

The Boston "Evening Traveler," of Oct. 19th, gave a full report of the sale of the herd of the late Alvin Adams, of Watertown, Mass., with the pedigree, name, and number of registry in the American Jersey Cattle Club Register, of 38 cows recorded in the book, with the names of the purchaser and residence; and also of 5 cows without pedigrees, with names of cows and purchaser, and the price each cow sold for, I find by this report that the five cows without pedigrees, or record, sold for a higher average price by about \$10 each, than those registered with authentic pedigrees. This report says, also, there were present about 800 of the Jersey stockraisers of the United States, etc., and that this herd was considered the finest in the country.

Admitting these facts, how happens it that the five cows, without record or pedigree, sold for a higher price than the Herd Register cows, except for the real reason, that they were the best cows, as they were, in all that makes value in a Jersey cow, viz., in form, size, udders, teats, colors, beauty, and all the qualities making value. I have conversed with several breeders, members of this Club, that were present at this sale, and they, without exception, all admit this.

The American Jersey Cattle Club, when it formed their Register, claimed that its object was to prevent imposition upon purchasers of Jerseys, by separating the pure from the mixed stock, or grades, that were sold for thoroughbreds. It was to be a purely philanthropic institution to prevent fraud. After years of labor, and sacrifice, and the collecting of thousands of dollars from the public, in the shape of entry fees to non-members of this Club, of

Fig. 5.—BORING RIMS.

\$3 on each animal registered, and the boast in one of the Club's reports, that an additional value of more than 50 p. c. had been given to every Jersey entered in this Register, in almost the suburbs of Boston, on the very spot where the Club originated, with this great company of experts, breeders, and judges, the cows without pedigrees, or record, out-sell those with pedigrees and record in this book.

[The writer of the above has perhaps singled out an exceptional case whereon to found a general rule. Any person who expects that pedigree alone will confer excellence, will probably be disappointed; but we imagine that Mr. Fitch himself places some reliance on the pedigree or descent of his own stock, even of those not recorded in the A. J. C. C. Herd Register.—Ed.]

Rustic Poultry Houses.

The most profitable poultry in the world are those of the Irish and French people. More eggs are exported from France and Ireland than from any other countries. The fowls of those countries are in greater part lodged in the most primitive sort of shelters, there being few, or none, of the costly buildings which in this country are generally supposed to be needed for profitable poultry keeping. The usual French fowl house is a little cabin of boards or bark, with a thatched roof, and a yard fenced in with small poles or brush. Generally

Fig. 1.—PLAN OF CHICKEN YARD.

there is a fruit tree of some kind, or more than one, in the yard. The Irish fowls are kept either in shelters made wholly of sods, built against the back part of the house, and warmed by the heat of the chimney, or the birds are accommodated with roosting places, along with the cow, in a part of the house itself. The hens are kept dry and warm, and this is the secret of their prolificness in eggs.

Fig. 2.—CLAMP FOR HOLDING HUB.

wheels soon begin to work, and open, water penetrates, the wood swells and shrinks alternately, and they very soon become an utter wreck. No

An illustration is here given (figure 2) of a very cheap poultry yard, similar to those we have often seen about the French farms. It is in three parts, and any number of compartments may be added. In each division there is a small, cheaply constructed house for roosting and laying. This is made low in the roof, for the purpose of warmth, and may hold a dozen fowls. For this number, a house four or five feet square, with roosts around three sides, will be large enough. If the floor should be sunk two feet below the surface, it would be warmer than if level with the ground. A few

Fig. 2.—ELEVATION OF CHICKEN YARD.

nest boxes may be hung upon the wall, so that the eggs can be removed through the window as well as the door. In the summer the window would be removed. A few nesting places may be made amongst the bushes, or trees planted in each yard. The ground plan is shown at fig. 1, on p. 56. Each yard may be 12 feet wide by 25 or 30 feet long. It will be found much better to keep the fowls in small families, of a few hens with one cock, than to have them all together in one yard; the cocks may then be changed each year. The doors to the yards are made in pairs, thus saving cost in making the frames. When desired, one lot of fowls may be given a run outside by leaving a gate open.

Hints and Helps for Farmers.

A FEED TROUGH FOR PIGS.—This (fig. 1) opens by a falling door in the front of the pen, and has an inner dividing board and partitions in the front, by which the pigs are prevented from fouling the meal, or fighting each other away. In this trough the meal can be kept before the pigs all the time, so that they can eat when they wish. There is a watering trough used with this pen, so arranged that one end is within, and the other outside of the pen. One pig, only, can drink at a time, and the water is not fouled. With meal and water, ready at all times, 2½ pounds of flesh has been put upon a pig in a single day.

FEED TROUGHS FOR POULTRY.—“W. L.,” Pontiac, Mich- igan, sends a drawing of a feed trough, (fig. 2), which he uses for his chickens. It is made of narrow boards with square ends, and to prevent the fowls from getting into the trough, and wasting the feed, he fastens a small post at

Fig. 2.—FEED TROUGH.

each end, and runs two cords, or wires, from one to the other, as seen in the engraving. This device is not so effective as that of the iron feed trough made by J. S. Spence's Sons, of Guilford, Ct.

Fig. 3.—IRON FEED TROUGH.

This, shown at figure 3, is of cast iron; it is provided with three flanges on the edges, two of which are double, and are tightened with screws. The wire cover, shown in the engraving, is fastened to these flanges, and prevents the fowls from wasting the feed. A large size may be used for feeding pigs. The troughs being of iron, and painted, are very cleanly and indestructible. We have used several of these feed troughs in our yards, and find the saving of feed will pay for them in one season.

A USEFUL FARM GATE.

—J. B. Berry, Casper Co., Mo., sends a plan for a farm gate, which he has had in use for 10 years, and which he made as follows: The posts (A, A, figure 4,) are of white oak sticks 11 feet long, and large enough to square 12 inches; these are squared for 7 feet, leaving 4 feet rough and round; the bark being taken off, the rough ends are set in the ground 10 feet apart, and 4 feet deep. The post holes are filled with dry earth, well tamped all the way up. In loose soil, it is wise to set a sill between the posts near the surface of the ground, to prevent sagging, but in compact soil this is not necessary. The 6 bars are 10½ feet long and 6 inches

Fig. 4.—PLAN FOR FARM GATE.

wide; the uprights at the ends (B, B,) are 6 feet long. These are arranged and bolted together at every lap, as shown in the engraving. A brace (C,) 11 feet long, is bolted on to the bars upon each side wherever they cross. The upright slat, D, is then

Fig. 5.—LOCK FOR GATE SHUT.

bolted on. The latch is 7 feet long, 4 inches wide, and thin enough to work easily between the braces where it is pivoted at E. It is raised by pressing on the handle, F. The hinges are then bolted on to

the side from the post, so that the gate will open completely back. They are seated upon pieces of wood fitted to the upper and lower bars to make them level with the upright bar. To prevent the latch being lifted by animals, a lock, L, is fixed to the gate. This is connected by a wire, M, to the lever, K. Another lever, H, is pivoted at I, and connected with the latch by a wire, J. When the

Fig. 6.—LOCK WHEN OPENING.

lock is out of use, the loop, N, is slipped over the lever, H; the latch will then work as if there was no lock. For the catch, a piece of 2 x 3 stuff is cut, as shown at A, B, C, fig. 7; the slope, B, being 4½

Fig. 7.—FORM OF CATCH.

inches long, the catch 1 inch deep, and the stem, C, 2 inches square. The lock, when closed, is shown at figure 5, and when open at figure 6.

A BRACE FOR A SLED TONGUE.—“J. K.,” Sullivan County, New York, gives a description of a brace for the tongue of a sled, shown at figure 8. This is made of two short chains, one at each side of a ring, which slips over the tongue, and rests against an iron bolt. The chains are hooked to the rings which are fastened on to the ends of the roller, as shown in the engraving.

Fig. 8.—SLED BRACE.

The Value of Crooked Timber.

When timber was plentiful many years ago, it was used without any thought of economy, or of the time when it would be worth saving. Then it was customary to use the finest pine, cherry, and walnut for fence-rails, and to split into slabs for making and flooring stables and pig pens; the best of the timber was used for this purpose, because it was most easily split, and made the smoothest and broadest slabs. Now timber is scarce and valuable, but we have not yet learned to use what is left to the best advantage. We use the straight timber for sawing, and burn everything that is crooked. For some purposes crooked timber is most valuable. Where it will pay to freight timber to places where ships are built, crooked timber is more valuable than any other. For ships' ribs, knees, etc., various kinds of bent timber are in great demand. But there are various uses for crooked timber on the farm, or for house-building.

Figs. 1 and 2.

A brace of bent timber of such shapes as are shown at figures 1, 2, and 5, would answer every purpose in a building that a straight one would do, and for supporting beams the forms shown at figures 3 and 4 would, altered slightly to make them right-angled,

serve as substitutes for braces, or if of light timber, would answer to fasten to rafters as feet to sustain the thrust of the roof against the plates. We have become accustomed to building with very light timber, and our houses and barns are worn

Fig. 3 and 4.

Fig. 5.

out and wrecked, before the generation which built them has passed away. By making use of heavier timbers, and working into them such crooked pieces for the purposes mentioned, our buildings would be many times more durable than they now are, and a farmer might then build a barn, which would last and be used by his grandchildren.

The mode in which such crooked timber is brought into proper shape for use, is as follows.

Fig. 6.—HEWING A KNEE.

The rough pieces, which are generally the roots, limbs, and crotches of trees, are laid upon some cross-piece and blocked up firmly, or are held so by "dogs," which grip the logs. The dogs are bars of iron half an inch thick, bent and pointed at the ends as shown at figure 7, and in use at *a*, figure 8.

Fig. 7.—DOG.

The timber is lined on the top with a chalk line upon the bark, which has been first "rossed" with the axe or adze, and is then notched down to the line, as shown in figure 6, at intervals of one or two feet—the distance depending upon the difficulty or ease with which the wood is split. The slabs between the notches are split off with the axe, as seen at the upper end of the piece shown in the figure.

Fig. 8.—THE SAW-PIT.

When all the slabs are split off, the surface is hewed smoothly with the broad-axe. This is being done on both sides, the timber is laid down, and the edges

are treated in the same manner. Where there is a hill-side, a saw pit may be made, as shown at figure 8. A few posts are set in the ground a short distance down the hill, and a timber is mortised or bolted upon them. Three or four timbers are laid from the bank so as to rest upon the frame below, as shown in figure 8. The log is rolled on to these cross timbers, and blocked or spiked fast with the dogs. A whip-saw is used to bring the timber into a finished condition. When the saw reaches one of the cross pieces, the log is lifted with bars so as to free the timber, and it is moved from before to behind the saw, and so on until the work is complete. Where a mill is distant and time can be devoted to it, a saw-pit of this kind may be made very useful upon many farms where there is timber to be cut for buildings, fences, posts, or other purposes.

Plan of a Saw Mill.

Several correspondents have requested a plan for a saw mill. This is an evidence of the fact that the *American Agriculturist*, while it is still, as it always has been, a journal for farmers and others engaged in the different branches of agriculture, is also extensively read by persons occupied in mechanical and other industries, many of whom are engaged in lumbering and saw-milling. When one of the common run of saw mills is examined by an expert at this business, there is evident a very frequent want of convenient and economical arrangement, and a great waste of power, both in consequence of the bad arrangement and the cumbrous, heavy, ill-constructed, machinery used. The old-fashioned overshot wheel, which utilizes only 50 per cent, or less, of the power, is generally found in country mills, in place of iron turbine wheels of the best construction, by which 75 per cent of the actual power is utilized, or instead of a well constructed steam engine, which can be fed and run at an almost nominal expense, by using the sawdust and other waste of the mill, and is not stopped by low water or freshets. The cheapest is not always the most economical. Utility and economy in use are to be considered before cheapness in the first cost, and there are now so many improvements in machinery, that can be had at so little comparative cost, that the miller can not afford to do without them. As an instance of this might be cited the "self-sets," by which, at one movement of a lever, or a winch, or in some by an automatic movement, the log can be set precisely at the proper point to cut a board or plank of any required thickness, with certainty; while by the ordinary "setting-bar" time must be taken to loosen the "dogs," move the log, adjust it by a measure, tighten the dogs, and then repeat

all this at the other end of the log; in the meantime the machinery has lost its momentum, and time must be given to restore this. The cost of the "self-sets" may be saved in a one-saw mill in one month, by the mere gain of time.

The plan here given is for the interior arrangement of a cheap frame mill, to be run by water or steam-power. The building is intended to be made in a bank or hill-side, so that the upper floor may be on a level with the log yard or pond and roll-way, and the basement may be occupied by lath and shingle mills, and the engines, if steam-power be used. In this case the boiler would be placed in the cellar, and all the waste of the mill would be carried through well-holes, slides, or hatchways, to the furnace. The principal floor is shown at figure 1. This is open at the front for seven feet in height,

and may be closed by drop doors. The floor should be at least 30 feet wide for a mill having all the machinery which is necessary to economical working. The length will have to be in proportion to the kind of timber sawed. A carriage of 30 to 36 feet long, will necessarily require a mill of at least double that length, and if any other machinery is used upon this floor, additional room will have to be provided for it. In the plan here given, the log-way (*a*) is at the side. The logs may be rolled in to the mill from a skid-way at the side, or may be drawn in at the front by means of a "bull wheel" and chain at the rear of the log-way. The carriage (*b*) is mounted on wheels, and runs on rails, by which less power is required than when the slide-ways are used.

The saw (*c*) is either a gate, a muley, or a circular saw; where hard wood is chiefly cut, the first is generally used, as being less likely to "run," than the muley or the circular saw, and needing less skill to work one passably well. At *d* is the gearing for the feed, and at *e* is the board-car and railway upon which it runs, either to the board piles in front or rear of the mill, or to the planing mill (*p*) in the rear. The rough edged boards from the sides of the logs, are edged on the table (*f*), and the slabs are run upon the board-car to the slab-saw (*g*), where they are cut into 4 feet lengths and thrown down the well (*h*) and slide (*i*) to the floor below, to be cut into laths. The edgings and thin slabs, when steam is used, are thrown down a hatchway to the cellar, where they are consumed under the boiler. Figure 2 is a plan of the lower floor, upon which is the slide (*i*) for the cut slabs, the "bolting" saw, and the lath-saw (*j*). In the rear of each of these saws a "horse" (*k*, *l*), is provided, upon which the bolts and laths are placed as they are sawed. When a bundle (50 or 100) of laths is sawed, they are tied up and the bundle placed upon a pile near by. A shingle mill may be placed at *g*, and supplied by the best of the slabs. The waste from these saws goes down the hatchway (*m*) into the cellar. The steam-engine (*o*) is above the boiler, and the large pulley and gears (*n*) are below the saws. Where the mill is run by water-power, this waste should be run out upon a truck and railway to a safe distance, where it is burned every day, so that it may not accumulate and endanger the mill by risk of fire. The shafting by which these saws are run, should go under the floor so as to avoid accident. There is now a great economy in purchasing what are known in the trade as complete saw mills. These are furnished by the manufacturers complete in every detail, from the engine and boiler to the belting by which the machinery is operated; so that it is only necessary to provide a suitable building to hold the machinery. There are several manufacturers who make a special business of supplying the machinery and fittings of saw mills, from whom estimates may be procured for outfits of all kinds, from the most simple up to the most complete.

Fig. 2.—LOWER FLOOR.

Fig. 1.—PRINCIPAL FLOOR.

NO NEED FOR INTERIOR FENCES.—The interior fences of farms occupy more space and cost more money, than the outer fences, while they are almost entirely unnecessary. In the majority of cases pasturing the cultivated land costs many times more than the little gain derived from it. The pasturing of mowing lands, and newly seeded stubbles, as a rule, is very injurious, and when, under exceptional circumstances, this is desirable, a temporary fence, of portable hurdles, might be profitably used. It may be beneficial to have a permanent pasture lot upon every farm, and where there is a roughish piece of land, it may be so used. But it will be found far more profitable to fence a

small plot in a convenient place for the stock, and feed them there with green-fodder grown and ent especially for them, than to make a practice of indiscriminate pasturing, with the necessary maintenance of interior fencing at a high cost.

A Hatching Coop for Winter Use.

Early chickens are very desirable, but they are troublesome to raise in the winter. To overcome the difficulty, and keep the young chicks sufficiently warm during very cold weather, we have provided a few coops of the style shown in the accompanying engraving. It is 4 feet long and 3 wide, and 4 feet high, which is large enough to give ample ventilation when it is temporarily closed. The nest is

A HATCHING COOP FOR WINTER.

made in one corner of the coop, and when the chicks are hatched, they may be confined in it when necessary. The front is a common hot-bed sash, 3x4 feet, and can be raised or removed at pleasure. The coop is placed in a corner of the poultry-house near the glass front, and being thus thoroughly warmed during the day, will retain sufficient warmth during the night. In the coldest weather a blanket or mat may be thrown over the coop.

A Village Improvement Association.—What has been Done in Litchfield, Ct.

In several villages of New England, there have been established of late, what are known as Village Improvement Associations or Companies. These consist of a number of public spirited, energetic, and liberal people—both ladies and gentlemen—who associate themselves under the operation of a State law, which regulates the formation of joint-stock companies without capital, for the purpose of improving the condition of the streets, side-walks, crossings, public squares, fences, shade-trees, and other conveniences and adornments of the villages. Every resident of a village knows how slowly reforms and improvements of this character are effected, and how difficult it is to induce some persons to see their interest in beautifying or improving, either their own or the public property. It is true, what is the business of nobody in particular, goes undone very easily, and that it is only by a great effort on the part of the more enterprising and enthusiastic citizens, that the indolence, or inertia rather, of the majority is overcome, and a course of improvement is set in action. The benefit accruing from the precept and examples of these enterprising people, are very great indeed; cleanliness, neatness, and order, are provocative of sobriety, industry, and thrift, and these again, tend towards a higher condition of morality. So that morality and comfort, as well as agreeable appearance, if not elegance, result from the operation of these village improvement associations. While they are desirable everywhere, they are still more useful and effective in those places where a large portion of the summer business is, to entertain strangers from the large towns and cities. These people are greatly attracted by clean streets, smooth walks, green lawns, bright gardens, neat houses, and the certainty of general order and respectability which these things indicate. Without distinguishing any one place in particular, there are many such villages as are referred to, which at first sight put the stranger upon good terms with them; while there are many which sadly need the

reforming influence of an improvement society, for their own good and for the comfort of those who visit them. For the benefit of the latter we give some account of the operations of the Litchfield (Conn.) Village Improvement Company. What has been done will speak for itself, and may serve to form a model for other villages to copy.

This Association was formed in April, 1875, and consisted at first of about 100 members. The first season there was expended \$2,147.73 in the following manner: 10,478 feet of concrete side-walk was laid; street crossings were made of stone, where formerly there was deep mud in wet weather, and deep dust in dry weather; seats were put up in the public parks; wooden bridges, (culverts we suppose are meant), were made; rubbish was removed, and railings were repaired. To meet these expenses \$1,412.29 was raised; of this sum, \$177 was from members fees; \$714.08 from entertainments of various kinds; \$129.83 from donations, and \$391.33 from repayments for side-walks. A debt was thus left to be carried over to the next season. The entertainments consisted of lectures, readings, and strawberry festivals, and were certainly liberally patronized. These, in themselves, were undoubtedly valuable aids to improvement, though not included in the original bill. In the winter of 1875-'76, walks were cleared of snow, and such shade trees as were broken or endangered by a severe ice storm, were trimmed. \$567.59 was expended that winter. During the second year \$2,214.91 was expended and the sum of \$1,923.69 was raised by similar methods to those already mentioned.

Besides all this work, much was done by private individuals, in emulation of the Improvement Company. Thus the example given by the Association, has led to a general disposition to improve the condition of private property, and as nothing is more infectious than a taste for flowers, green lawns, neatly kept foot-paths, and fences, the desire to improve spreads beyond the village, and the farmers outside begin very soon to adopt the general custom. It is easy to conceive how far this may go when it is once started, and what an immense influence for good is exerted far and wide. In beginning this improvement, it is the first step which is the most difficult, and this must be taken by one energetic and experienced person. This was the case in the instance here referred to, but it was fortunate that his efforts were readily supported by others. It is to be hoped that this example may be copied in many villages, and although it may not always be possible to enlist so large a company of helpers, yet a small beginning should not lead to discouragement, as proportionate success may be achieved. The profits resulting from these improvements, are far greater than the original cost. Not only is there a direct value received for the money expended, in the increased worth of the property benefited, but there is, besides, not estimating the resulting comfort and satisfaction, a large extra value added. A well kept garden, neat fences and gates, and shade trees, add to a village lot or a farm, many times their cost, so that no more profitable outlay than this can be made.

A Bolster Spring for Farm Wagons.

A new Bolster Spring is shown in the accompanying engravings, which possesses several good qualities, not the least of which is, that a set may be bought at a moderate price, and attached to the

Fig. 1.—SPRING FOR WAGON BOLSTER.

wagon by the farmer himself. The desirability of having springs to wagons for heavy work need not be urged; the saving in wear and tear of both wagon and wheels is large on even good roads, and as our roads are generally the reverse of good,

there are but few localities in which these springs would not pay for their cost in the increased durability of the vehicle. The springs, figure 1, are attached to the wagon-box, as shown in figure 2, and rest upon the bolster; such is their shape, that the box is raised only three inches above the bolster. The springs can not break, as before their whole tension is exercised, the weight of the load rests upon the bolster, and thus the springs are relieved from sudden jerks caused by stones or

Fig. 2.—THE BOLSTER SPRING ATTACHED.

ruts in the road. The use of these obviates the necessity for having springs to the wagon seat; they are made to carry from 2,000 to 5,000 lbs. the set. This very recent invention, which will meet a general want, is just brought out by the makers, Semple, Birge & Co., of St. Louis, Mo., widely known as builders of wagons and farm machinery.

The Hereford Breed of Cattle.

BY T. L. MILLER, BEECHER, ILL.

In an article in the *American Agriculturist* for November last, accompanying an engraving of the Hereford bull "Little Bill," it is stated that the Hereford is "second only to the Shorthorn as a beef animal, when kept under equally favorable circumstances." I have now been a breeder of Herefords for several years, and there is no place where the Shorthorn can excel the Hereford. The Shorthorn shows at his best when on the richest food, and all he will take of it, from the time he is dropped until he goes to the butcher. Even here the Hereford will make as large gains as the Shorthorn, and do it on twenty-five per cent less feed. And the larger portion of the writers on cattle, when they touch this point at all, admit a difference in favor of the Hereford. The only place where the Hereford and Shorthorn have an opportunity to test this, has been at the celebrated cattle fairs at Smithfield, Eng. For nearly the whole time, from 1799 up to 1851, the two breeds were shown in the same classes—in fact, all breeds were shown together—and the Hereford oxen, or steers, as fat cattle, took 185 premiums, as against the 82 by the Shorthorns. The Herefords were formed in the hands of Mr. B. Tompkins, commencing in 1766, and fairly established 1776—about the same time Charles & Robert Colling were improving the Shorthorns. As a rule, the feeders and breeders that show at Smithfield, have fed high, and it is fair to presume that the two breeds have made the best weights and quality that could be made, while the Herefords took nearly twice as many premiums as the Shorthorns, and nearly twice as much money. If the test could have been made as to the cost of producing these weights, then the Herefords would have shown at least twenty-five per cent better than the Shorthorns, and many of the feeders of Herefords would claim a greater difference than this. A late Shorthorn paper admits these facts in favor of Herefords at three years and over, and claim an advantage for the Shorthorn at two. The same article admits that Hereford beef in the London market, at three and over, is worth more than Shorthorn beef, and that every where good butchers will pay more for Hereford than for Shorthorn beef. Now, what are the facts, we will take Smithfield again. The beef steers are

shown in classes as follows:—Under 2 years and 6 months; over 2 years and 6 months, under 3 years and 3 months; over 3 years and 3 months, under 4 years and 6 months. In 1869, in the youngest and oldest classes, the Herefords were the heaviest, but the difference of weight at the Smithfield between the Herefords and Shorthorns, is trifling, and is

of the dairy, are appearing almost daily, and in this respect dairying is not at all behind any other skilled handicraft. But to curdle the milk, rennet—the stomach of the calf—is still used; and the curd is heated in the vats, broken up; drained, ground, salted, and pressed, the same now as in the old-fashioned dairies. The greater economy of

test; this is to take a bar, or rod, of iron heated to a point somewhat less than a dull red heat, and bring it into contact with a piece of curd. If, when the hot-iron is drawn from the curd, it brings with it a quantity of glutinous strings, the curd is ready for removal from the vats. It is dipped out from these with the curd dipper, a pail having a flat side,

Fig. 3.—STIRRING THE CURD.

Fig. 4.—TAKING CURD FROM THE VATS.

as often with one as the other. The great difference between the Hereford and Shorthorn is in the cost of production and the value of the product. The cost of production is one-fourth in favor of the Hereford. The product is worth from ten per cent to fifteen per cent in the Hereford more than in the Shorthorn steer, and these points should always be borne in mind. And again, the Hereford can be grazed and fitted for the butcher on pastures that would not keep a Shorthorn even in good store condition. These facts can be sustained.

[While Mr. M. may believe the above to be all perfectly true, yet the fact that there are hundred Shorthorn herds in existence for one of Herefords, must be taken to prove that, for some very good reasons, the Shorthorn is superior to the Hereford. Fashion must have something to back it.—ED.]

The Process of Cheese Making.

The establishment of the factory system in the cheese dairy, has made no change in the method of

labor in the factory, however, is seen at once in glancing over the apparatus used. After the receiving and weighing of the milk, as shown in an illustration upon page 53, it is run into vats, which hold about 600 gallons each. In these the milk is warmed to about 80°, the proper temperature for coagulation; it is then well stirred to ensure the even distribution of heat, and the rennet is added and thoroughly mingled by stirring. The curdling is complete in 40 to 60 minutes, when the mass is stirred, or broken (fig. 3), by a many bladed curd knife into small blocks to facilitate its separation from the whey. When the curd has acquired sufficient firmness, it is more thoroughly broken, either by the hands or by what is known as an agitator. After the curd is broken up, heat is applied by means of steam pipes until the whey and curd together are brought to a temperature of about 100 degrees. During this heating the curd is stirred, and after the "cooking" is complete, it is left to rest, with occasional stirrings, until a proper degree of acidity, or rather approach to acidity, is observed in the whey. The whey is then drawn off, and the

into a cooler, the vat being tipped by means of winches. This is shown at figure 4. The curd is left here to cool for a few minutes, when it is turned over and again left, to acquire a certain mellowness. It is then pressed for 10 minutes, when it is taken out, ground in the curd mill, (fig. 5,) and salted; two pounds of salt being used for 100 pounds of curd. The proper temperature of the curd is kept up during these processes by covering it with a cloth. After having been ground, and salted, the curd is put into the presses, (fig. 6,) in which it remains under pressure for two or three days. The pressure, which is regulated by means of a screw, should be sufficient to force out the whey, and consolidate the cheese. It is obvious that much tact and experience are needed to produce cheese of first quality, when it is considered what a multitude of interfering and complicated changes may occur in the condition of the curd, through atmospheric effects, the quality of the milk, or the rennet, or unavoidable difficulties in securing the precise degrees of heat or fermentation of the curd. But in the well managed cheese factory all danger of

Fig. 5.—GRINDING THE CURD.

Fig. 6.—PRESSING THE CHEESE.

producing the curd from the milk, or the cheese from the curd. The improvements have been wholly in the machinery used in the processes; and in this respect the apparatus of the factories is constantly changing for the better. New contrivances for performing labor more easily, or for securing greater cleanliness or effectiveness in the methods

curd is heaped in the vats and left to become sour. Upon the exact degree of acid that is developed in the curd, depends, in a great measure, the quality of the cheese; and the skillful practice of an experienced cheese maker is perhaps more needed just here than in any other part of the process. Those who need it can use what is known as the hot-iron

failure is reduced to a minimum, as compared with the chances of a hundred small dairies all differently managed, and without the machinery needed for accurate manipulation. It is on account of this uniformity in quality that the American factory cheese fills a place in the markets of the world that no other dairy product has ever done, or is likely to do.

Macowan's Flame Flower.

The well known *Tritoma Uvaria*, its varieties and allies, is justly valued for its brilliant spikes which give a brilliancy to the garden in the autumn months. We are indebted to England for the common name, "Red-hot Poker Plant," which is

soft orange color, which is very pleasing. The plant seems to be a remarkably free flowerer, and its season is evidently a long one. The stems of tall species, unless staked, are apt to be bent by the weight of the flower spikes, and the autumnal storms frequently make sad work with them, accidents from which this species is likely to be free. When first introduced into England, it was grown

servedly one of the most popular of ornamental-leaved bedding and pot-plants; and being easily propagated, a sufficient stock is quickly obtained to meet the great demand which a desirable novelty like this is sure to create. The now well-known variety called "The Shah," which for some time after its introduction seemed to be "under a cloud," has at length proved to be invaluable for bedding

MACOWAN'S FLAME FLOWER.—(*Tritoma Macowani*.)

MANY-COLORED COLEUS.—(*Coleus multicolor*.)

more descriptive than elegant, and when the English, as we see by their journals they are disposed to do, change this awkward name to "Flame Flower," we are quite ready to accept the amendment, with thanks. The plants were originally placed in the genus *Kniphophia*, but later a portion of them were separated to make another genus, *Tritoma*. We notice that English writers are of late inclined to restore these, and to call them all *Kniphophia*. As the name *Tritoma* is well established in our gardens and catalogues, we retain it until we can examine into the reasons for discarding it for the other. Our purpose is not to discuss names, but to call attention to a new species, so recently introduced into cultivation, that it is quite a rarity abroad, and which we saw last October flowering finely in the hardy herbaceous collection of Messrs. Woolson & Co., Passaic, N. J. This species was discovered by Prof. Macowan, in the mountains of South Africa, at an elevation of 4,500 feet above the sea, and was named in his honor, *Tritoma Macowani*. With the same general appearance as the tall-growing *Tritomas*, which have been so long in cultivation, it is much more delicate, and smaller. The leaves differ from those of the other species in being more rigid, and in having their edges roughened by minute teeth. The flower stems are not much over a foot high, (the English descriptions say from 1 to 2 feet,) and bear at the summit a spike of reflexed flowers, which, while they have not the fiery aspect of the other species, are sufficiently brilliant, being of a very rich and

only as a conservatory plant, for which use it is well adapted. It has proved quite hardy with Herr Max Leichtlin at Baden Baden, Germany, and in some English gardens, and will be tested by Woolson & Co. the present winter. The other species of Flame Flower are usually hardy in the climate of New York, if given a covering of litter, and this species of Macowan is so desirable that, if not absolutely hardy, it will be worth the slight protection required by the others.

A New Coleus.—C. Multicolor.

BY W. C. BARRY, ROCHESTER, N. Y.

[Last fall we saw at Ellwanger & Barry's a new Coleus, which Wm. C. and Charles Barry, who had recently returned from Europe, had brought over "by hand," so to speak, as they had cared for it in their state-room during the voyage. The variety being quite new, we requested Mr. Barry to furnish us, when the plant should be sufficiently recovered from the effects of travel, with materials for an engraving; this he has done, and at the same time sends the accompanying notes.—ED.]

Of the many Plant "Novelties" which I had the pleasure of seeing while abroad the past summer, I think that the most interesting and valuable was *Coleus multicolor*. Interesting, because of its curious, distinct, and beautiful foliage; valuable, for the reason that in this climate the Coleus is de-

out as well as for pot culture. The "Chamelcon," another beautiful variety, about which there was some question as to its value, has won its way to popular favor, and is now considered indispensable in every collection. The new species, the form of which is represented by the engraving, is very appropriately called *multicolor*, on account of the many colors which are presented in its leaves. Although quite distinct from either of the varieties mentioned above, it seems to partake to some extent of the peculiarities of both, so much so as to suggest that it may have originated from them. It is claimed for it, however, that it is a distinct species, and a native of the Solomon Islands. It was introduced to the trade last spring by the celebrated firm of Veitch & Sons, London, who describe it as follows:—"In form the leaves differ chiefly from the usual type in having the teeth of the edges greatly elongated and rounded at the tips. In color it is remarkable for the number of rich shades of crimson, red, rose, etc., into which the leaves sport; some of the young leaves having also a bright yellow for the ground color marked with rose or red. All the shades of color in the foliage contrast finely with the bright green of the stem and foot stalks. It is a very beautiful plant, and will be found among the most useful of its tribe for decoration. It received a First Class Certificate from the Royal Horticultural Society, May 2nd. Also a Certificate of Merit from the Royal Botanic Society, April 18th."

All who have seen the new Coleus pronounce it a valuable acquisition to the list of plants with orna-

mental foliage, and if we mistake not, it is destined to meet with a cordial reception in this country by all the lovers of new and beautiful plants.

Experience With Vegetables in 1877.

BY PETER HENDERSON.

[As an aid to those who, bewildered by the great variety offered by the catalogues, find it difficult to make a selection of vegetables, we have usually given in February a list of those we regard as reliable. While it is desirable that the main crops should be of sorts, the value of which is well established, we would not discourage the trial of novelties, of which many are offered every year, the testing of these in comparison with the older kinds adds much to the interest of gardening. This year, Mr. Henderson gives us the results of his experience, which in the main agrees with our own.—ED.]

For a number of years past we have set apart a piece of our ground on Jersey City Heights, N. J., for testing the relative merits of all the leading kinds of vegetables in general use. Every class is treated exactly alike. All of each class are sown the same day, and in every subsequent operation, the greatest care is taken that all are treated alike, whether sown in hot-bed to be transplanted, or when sown in the open ground. Our "Trial Book" shows the following results of the various tests. We name, however, only the varieties having merit, all such as were tested and found to be inferior either in earliness or quality, are either not named here at all or merely noticed to indicate, wherein, in our estimation, the want of merit lies. About an average of 25 varieties of each kind of vegetables were tested, and at least 50 plants of each variety:

Beans, Bush.—Early Mohawk is a few days earlier than Valentine, which is yet the best for general crop. Black Wax is a fine stringless variety. Refugee, late and largely used for pickling.

Beans, Pole.—Large Lima is still the favorite. Dutch Case Knife is also an excellent sort, and the Giant Wax is a stringless snap bean, but a climber.

Beets.—For first early we find Egyptian best, next the Blood Turnip, and for late the Long Blood. Bassano is early, but objectionable for market, on account of its very light color.

Mangels and Sugar-Beets.—In an impartial trial of the four best known sorts, Norbiton Giant gave 20 per cent more weight per acre than any other.

Cabbages.—The seeds were sown in hot-bed on March 1st, and the plants set out in the open ground the first week in April. The Early Wakefield still stands unrivalled as earliest and best of its size, it being in fine marketable order on June 15. Early Summer, however, that came only one week later, was double the weight, and equally uniform in heading. This we find is becoming the favorite large early variety in almost every section of the country. It has only been introduced into general cultivation within the past four years, though it has been grown for nearly 20 years by one of our best Long Island farmers, who had a monopoly of it up to that time. Next in value, as a second early, comes the Winningstadt, a well known pyramidal-shaped variety of great solidity. Next in order came Early Flat Dutch, which, by middle of July, gave heads of 15 lbs. weight. For the fall crop, (seed sown in May,) nothing is found better than Premium Flat Dutch. A correspondent in Pennsylvania writes that a field of 5 acres averaged 14 lbs. per head. American Drumhead Savoy is best in its class. Of cabbages for pickling, we find the Blood Red Erfurt by far the best colored.

Carrot.—French Forcing, earliest, and handsome, next Early Horn, and a newish sort called Half Long Red, of very bright color, and excellent flavor. For field crop, Improved Long Orange is best.

Cauliflowers. (sown and planted at same dates as the cabbages.)—The new variety known as Early Snowball, is the best acquisition of the season. It was a week earlier than all other sorts tried; heads of fine size, of snowy whiteness, few and short leaves, making it in every way desirable, whether for growing under glass or in the open ground. Next to this was the Extra Early Erfurt,

hitherto considered the best variety. Later, for succession, came Half Early Paris, and Le Normand's Short Stemmed, too late for early, but valuable as a fall sort.

Celery.—Probably in no vegetable cultivated has the variety so much to do with success as Celery. Our own experience, and that of scores of our immediate neighbors, is that nearly all the giant or tall-growing kinds are unprofitable to raise. Not only does their culture entail twice the labor, but they are almost always wanting in solidity and in flavor. While some hundreds of acres of Celery are now grown for the market of New York, the kinds are mainly the Half Dwarf and Dwarf Sandringham, in the proportion of four of the first to one of the second. The Boston Market variety has never been a favorite for the New York Market, as its tendency to throw up suckers, or side shoots, considered the merit of that variety in Boston, makes it objectionable here. Hood's Dwarf Red is the best variety of Celery in cultivation, but the American public, with few exceptions, will not use red Celery, while in England it is highly valued, as it should be, for it is not only much better flavored than the white sorts, but it keeps better, and surely, when used as an ornamental vegetable, as Celery often is, its bright crimson, and white color, make it more attractive than the white.

Corn.—Minnesota we find to be the earliest variety of good size. The habit is dwarf, size of ear medium, very productive, and sweet.... Large 8-rowed, second early, large size, sweet.... New Egyptian, this variety is of large size; is about as early as 8-rowed. The merit claimed for it is its excellent flavor. It has been but little grown outside of Baltimore, but has been cultivated there for several years to the exclusion of nearly all the other sorts.

EARLY SNOWBALL CAULIFLOWER.

...Stowell's Evergreen for late main crop we find nothing yet to supersede this old and reliable kind.

Cucumbers.—Early White Spine, and Green Prolific, were earliest and most prolific, while for pickling, Early Cluster and Short Green seem best.

Egg Plant.—New York Improved is rather earliest, but Black Pekin is to our taste the best flavored—they are nearly alike productive.

Endive.—Moss Curled, Green Curled, and Batavian. **Lettuce.** (sown and planted same date as cabbage.)—We find All the Year Round (one of the cabbage or Butter class) headed first. Next came the Simpson, and next for standing the hot weather best were Large White Summer, and Curled India. Boston Market, though rather small for out-door culture, is now almost exclusively grown as the best for heading under glass.

Musk Melons.—White Japan proved earliest, but for general crop Nutmeg and Green Citron are preferable. Cassaba is a large yellow kind; is of excellent flavor, and very prolific.

Onions.—Wethersfield Red, Yellow Danvers, and

White Globe, are probably the best of their colors, for general culture, though the newer kinds of the Italian varieties, such as White Tripoli, Queen, and Giant Roeca, grow finely in South and South-western States.

Parsnip.—Hollow Crowned.

Parsley.—Moss Curled and Double Curled.

Peas.—These, like Tomatoes, have so many new claimants for earliness and productiveness, that it is not easy to decide. Our tests of last season place them as follows, as near as we could judge: First, Improved Dan'l O'Rourke, next Philadelphia Extra Early, and Carter's First Crop for round peas requiring brush. Of the Dwarfs, Little Gem and Blue Peter, while for larger growing wrinkled sorts, Alpha is best and earliest; while for main late crop nothing yet we find as good as Champion of England.

Radishes.—Scarlet Turnip, Long Scarlet, and the new White Tipped Scarlet, (French seed,) are all about equally early. The last named is very distinct and pretty, and in every way desirable. Of the late or winter Radishes, the China Rose Colored, Black, and White Spanish are all good.

Spinach.—We find that the Savoy-leaved is by far the best, giving nearly twice the weight of crop on the same space. It is somewhat singular that the great value of this variety seems to have been overlooked by the market gardeners of New York, and they have only recently woken up to it on seeing it sent in by the growers from Norfolk, Va., and other Southern points.

Tomatoes.—Sown March 5th, were carefully transplanted twice, and set out in open ground May 20th. This was the most puzzling trial we made, as it was difficult to impartially pick out 3 or 4 as the best among so many. Canada Victor was, by a majority of censors, judged the earliest and best, though Conqueror and New York Market resemble it, and they are evidently all nearly allied to each other. Arlington, a valuable variety, but little later, is exceedingly prolific, large, and smooth, and this and Excelsior are the favorite varieties for canning. Trophy is late, but its other excellent qualities still leave it the field. Golden Trophy, a beautiful yellow variety, is in every way worthy of cultivation. The very early varieties, such as Little Gem, 100 Days, and Key's Prolific, ripened a few fruit 10 days before those above named, but all these varieties are worthless for market purposes, because the difference in earliness of 150 miles farther South, brings in the finer sorts, cheap enough to take their place until the better sorts ripen. I have but little hope in any farther improvement in earliness of the Tomato. We have made no advance on Key's Prolific, sent out 7 or 8 years ago, and that earliness was at the expense

of both size and quality, while in the good market sorts it is doubtful if there is anything much in advance of a good stock of New York Market, which has been in culture for 25 years.

Turnip.—Red, and White-Top Strap-leaf are earliest. Purple White Globe is nearly as early, and will prove a more marketable sort from its larger size. Yellow Globe, for second early, is one of the best for general crop. In *Ruta Bagas*, the American grown seed of the Purple and Green Top kinds proved better in every case than some half dozen kinds of imported varieties tried, with the exception of the Long White French, a variety of excellent flavor, and otherwise desirable.

The Fern-Leaved Trumpet-Flower.

Last spring, Mr. John Saul, of Washington, D. C., who has a way of sending out novelties at a very early date, sent us, among other new plants, a specimen of *Campsidium filicifolium*—a good deal of a name for such a bit of a plant, as it was. We knew

it was one of the new plants for which Mr. Bull had certificates from the London Societies, but did not give it special attention at that time. Indeed, the *Campsidium* went quite out of mind until last fall, when at Rochester, Mr. W. C. Barry called our attention to some fine specimens in the extensive greenhouses of Ellwanger & Barry. Mr. B. was quite enthusiastic over its beauty, as well he might be, and predicted for it great popularity. When we returned home, we looked for our own specimens, that came from Mr. Saul, and were glad to find it had grown to a vine two or three feet long, and clothed with leaves of the most graceful kind. The engraving will show the character of the foliage; according to the English catalogues, the leaves grow to the length of about five inches, though on our small plant they are only about half that; each leaf consists of six to twelve pairs of small leaflets, with a terminal one, these leaflets are lobed and toothed, and, being of a fine green color, the foliage has a strikingly fern-like aspect, and reminds one of some of the aspleniums. Its very beautiful foliage, and the delicate, twining stem, makes the plant a most admirable one for decorative work, especially for vases and baskets, where it can hang gracefully down the sides. It is suited to many of the uses, to which *Myrsiphyllum*

FERN-LEAVED TRUMPET-FLOWER.

(*Smilax*) is put, and is superior to that in the greater delicacy and variety of its foliage. We notice that in England it is classed with the stove-plants, but ours appears to flourish in the greenhouse. It is said to bear cutting well, pushing out a new growth freely after it had been cut back; another point in its favor is the ease with which it may be propagated from cuttings. Should it become as popular as it promises to be, no doubt our florists will soon find the best manner of managing it, to supply it in such quantities, as they now do the deservedly popular "*Smilax*." The plant is a native of the Feejee islands. A word as to the name we have adopted. The flower is not known, and when the plant was received in England, it was called a *Campsidium*, from its resemblance in habit and foliage to other species of that genus, and the descriptive specific name, *filicifolium*, or "fern-leaved," was given to it. But the best botanical authorities do not admit *Campsidium* as a genus. Benthams and Hooker find that it is not distinct from *Tecoma*, the genus of our "Trumpet-flower." Hence if, when the flowers and fruit are known, it should be found that its relationships were properly inferred, from its foliage, its correct scientific name will be *Tecoma filicifolia*, which readily Anglicises into "Fern-leaved Trumpet-flower," a name under which it will stand a much better chance for popularity, than if it is to be *Campsidium filicifolium*. But our name, like that, depends upon an if.

THE PAMPAS GRASS.—The plumes of this stately grass have been sent from California this fall in large numbers, to New York and other Eastern cities. Nothing can be finer in the way of orna-

mental grasses, than these spikes, about a yard long, of a dense wavy mass of silken florets and hairs, of nearly pure white. This grass (*Gynerium argenteum*) is dioecious, the pistillate or female spikes, being greatly inferior to the staminate in size and silkiness, so much so that some dealers supposed that another grass had been sent to them. The Pampas Grass must be cultivated largely in California, probably expressly for these plumes, which appear as if they had been exposed to sulphur fumes, as they are much whiter than we have seen them elsewhere. The first consignment sold at \$3 for a pair of plumes, but later they came in such quantities and so variable in quality that dealers offered them at \$1 and less. This grass is scarcely hardy at New York, though it may usually be kept through the winter by giving the roots a covering. A cask placed over the clump, filled with leaves, and covered with boards to shed rain, makes a not very slightly, but an efficient covering.

A Double Crop—Cauliflower and Lettuce.

BY PETER HENDERSON.

In the vicinity of our large cities there are acres of glass devoted to the forcing, or forwarding, of lettuce, radishes, etc. The principal crop, however, is lettuce, which is raised during the winter months, either in the old-fashioned hot-beds, heated with stable manure, or else in the more recent greenhouses, heated by hot water pipes. But by far the largest quantity of early or forced lettuce is grown in the "cold frames," such as are used for keeping the plants over winter. These are simply two boards set on edge, and placed parallel to one another. The one at the back being about 1 foot in height, the front one about 9 inches; the distance apart being according to the length of the sash, which is usually 6 feet. These frames are always placed in a position naturally sheltered from the north-west, or else a high board fence is built to shelter them. The soil is pulverized and enriched in the best possible manner, and the lettuce is planted usually (here) about the first week in March, or nearly a month before operations can be begun in the open field. When the ordinary size or sash (3 x 6 feet) is used, about 50 lettuce plants are set under each sash, or 5 rows of 10 plants in each, as shown in figure 1. But when a double crop of lettuce and cauliflower is grown under the same sash, they are planted, as shown at figure 2, with three entire rows of lettuce, and three of the lettuce plants in the other two rows replaced by cauliflower, the cross (x) showing where the caul-

1. SASH OF LETTUCE. 2. LETTUCE & CAULIFLOWER.

flower plants are placed. Thus planted, each sash contains 44 plants of lettuce, and 6 plants of cauliflower.... Presuming that both are planted on March 1st, and protected in the usual way with sash, the lettuce will be fit for use, and cut out by about May 1st, leaving the whole space in the frame to be occupied by the six plants of cauliflower, which, at this season, protected by the glass, will

now grow so rapidly that it will be necessary to add to the frames another board in height, so as to give it head room. With proper attention to airing and watering, an excellent crop of cauliflowers is almost certain by the end of May, or about three weeks sooner than it would mature out-doors, if it matured at all; for all cultivators know how precarious a crop cauliflower is when planted in the open ground in our hot, dry June weather. In England the crop rarely fails, when planted in spring out-doors, for there they get very nearly the conditions of temperature which we give when forwarded under glass in the way above described.... The advantage of this double crop is apparent. Only six plants of lettuce are lost by the presence of the cauliflower, while three weeks longer use of the sash matures the cauliflower, which at that season readily sells in New York at from \$6 to \$9 per dozen, and by averaging the lettuce at \$5 per 100, a moderate estimate for the double crop of lettuce and cauliflower per sash, would be \$5. The variety of lettuce used is the Boston Market, and of cauliflower, the Early Erfurt. Though the new dwarf sort known as Snowball, will probably, with its compact growth and short leaves, do even better.

The Crossing of Lilies.

BY PROF. ASA GRAY.

Mr. Francis Parkman is famous as a horticulturist as well as a historian. In a new number of the "Bulletin of the Bussey Institution"—of which he was formerly Professor of Horticulture—he has now given the history of his "Hybridization of Lilies," carried on for ten or a dozen years. He began by crossing two superb Japanese Lilies, *L. speciosum* and *L. auratum*. The first year he failed; the second year brought one splendid success; for it gave us that superb lily, twelve and even fourteen inches from tip to tip of the extended petals, which, when sent to England, astonished the horticultural world, and which there received the name of Parkman's Lily (*Lilium Parkmanni*). The other results obtained in this and the succeeding operations, were of little or no practical value, but were as surprising as the Parkman Lily is magnificent.

We expect offspring to take after both parents, a hybrid to inherit somewhat equally the characters of the two species that compose it. That was the case with the Parkman Lily, which has the fragrance and form of *L. auratum*, and the brilliant color of the best races of *L. speciosum*. But this was the result in only one case out of more than fifty. Every other seed that germinated and lived to bloom, produced flowers exactly like those of the female parent, *L. speciosum*. But they were hybrids nevertheless. Mr. Parkman took all the necessary precaution to prevent access of own pollen; and the seedlings showed the blood of the male parent in their stems, though not in the blossom; for these were mottled in the manner characteristic of *L. auratum*. Though the male parent showed for so little in the first generation, there was reason to hope it might be impressed on the second. So Mr. Parkman fertilized several of these hybrids with the pollen of *L. auratum*, precisely as their female parent had been fertilized. The result was a very little seed set, but enough to produce 8 or 10 young bulbs. Of these, when they bloomed, one bore a flower combining the features of both parents. All the rest bore flowers not distinguishable from those of *L. speciosum*.

Was this inordinate habit of taking after the mother only, or mainly, a peculiarity of these two species, or was it a character of Lilies generally? To settle that question, Mr. Parkman crossed *L. umbellatum* with the pollen of *L. auratum*. The progeny was not to be distinguished from *L. auratum*, yet showed its hybridity in the imperfect condition of the stamens of many of the blossoms, and in the abortion of the pistil of some of them. Next he crossed *L. longiflorum* with the pollen of a deep red variety of *L. speciosum*. Seeds were abundantly formed; but the plants raised from them produced the flowers of the female parent, unchanged, the pure white being without tint or spot. Some of these he now crossed with *L. au-*

ratum, in some instances successfully; but in the offspring neither *L. speciosum*, their grandfather, nor *L. auratum*, their father, had produced any effect whatever on the pure white of their petals; yet the anthers had been affected, taking a chocolate tinge from the father; and as before many of the flowers were imperfect. Some of the best of these flowers were now tried in the third generation, with pollen both of *L. auratum* and *L. speciosum*; but not one would bear seed.

Moreover our American *Lilium superbum* was fertilized, under every precaution, with the pollen of six foreign species; seeds were abundantly produced in some instances, though in many the pods contained only chaff; several hundred bulbs were raised, but when these came to bloom, not a single flower of them all was distinguishable from that of the pure *L. superbum*. Nor in this case was there any mark of the male parent to be found in the stem, or leaves, or bulbs. All this is very curious indeed. We knew that offspring might take a great deal more after one parent than the other. But that the female sex should be so prepotent in Lilies, is a quite unexpected result. That in so many cases the influence of the male parent should be imperceptible is most wonderful.

THE HOUSEHOLD.

For other Household Items see "Basket" pages.

Light in the Dwelling.

One need not be very old to recollect when kerosene, or some other product of petroleum, or coal, was first introduced. What a blessing it has been! Formerly one of the attractions of city or town life, was the ability to use gas, but now the humblest farm-house may be quite as brilliantly, and more pleasantly lighted than the most costly city dwelling. The blessing is so general, and so much a matter of course, that we hardly appreciate it, but let us put aside our lamps and use the tallow dips, or even the lard-oil lamps, or the "star," or other candles, for one evening, and we shall be very unwilling to return to them. Even the commonest kerosene lamps are a great improvement upon any mode of lighting that had gone before, and the great benefits of kerosene—which we use as a general term for the best illuminating oil—were to the farmers, and their families, rather than to those who lived in towns large enough to sustain gas works. With the brilliant light now at command, the evening is made much more valuable to the

CLEVELAND SAFETY LIBRARY LAMP.

farmer and his family. Aside from the general increase of cheerfulness which abundant light brings, reading and study can go on quite as well—in fact, better than in day time—for in the day, an active person feels that he should be out, and astir; the

evening seems the proper time for study, and our present light is a great help. When we have a good thing we like to tell others of it, and seven years ago this month, we described and figured (Feb., 1871) the "German Student Lamp." We had been temporarily residing in the city, and though the house was supplied with gas, we used this lamp with kerosene in our study, as being in every respect, including cheapness, greatly superior to gas. The article was written after two or three years' use of the lamp in the country, and having that, we did not feel any inconvenience from the absence of gas. While the "German Student Lamp" seemed nearly perfect, there were some inconveniences attending it, especially in the device for raising and lowering the wick—which sometimes would work, and at other times would not. The mechanical arrangement for this purpose was crude and imperfect, and that was the only fault in a lamp that gave a light for study use, far superior to any gas-burner we ever met with. Recently we have been using the "Cleveland Safety Library Lamp," made by the "Cleveland (Ohio) Non-Explosive Lamp Company," and we can apply all our commendations of the "German Student Lamp" to this—and a little more besides. The difficulty we found with the other lamp—the management of the wick—has been completely removed in this. The mechanical arrangement for controlling the flame is perfect in its working, and the amount of light is easily and certainly adjusted. The lamp, of which an engraving is here given, has the same general appearance of the "German Student," but the oil reservoir is much larger, and less frequent filling is required. All the metal-work is nickel-plated, thus insuring an elegant appearance, and ease of keeping it in order. The "Cleveland Non-Explosive Lamp Company," who make this lamp, apply to the font which holds the oil, as they do to all other lamps made by them, a safety guard of wire gauze, to prevent explosions in case unsafe oil is used. While it is well enough to have this, absolutely safe oil is now so easily to be procured that we can not advise the burning of any other in any lamp. If there is any lamp for burning kerosene that will give a more satisfactory light than this "Library Lamp," we should be very glad to make its acquaintance.

Home Topics.

BY FAITH ROCHESTER.

Putting Children to Bed.

Ten years ago an old friend told me that her babies had cried more over going to sleep at night, or taking their daily naps, than about all their other troubles put together. She said this after expressing surprise at the cheerful way in which my year-and-a-half-old boy went up stairs for a nap, and the quickness with which I returned to the parlor. Possibly she followed too strictly advice often given in print to mothers, something like this: "Have a regular hour for the child's nap, or for its bed time, and when that hour comes, put it in its little crib and leave it there to go to sleep without further attention." Bad advice, I think.

Being of a tender heart, my friend more likely rocked or soothed it to sleep herself, but the attempt to establish regularity may have been very trying to both mother and child. I came very near carrying this thing too far myself. Regular habits, for children of all growths, are an excellent thing in most respects, but their formation should be coaxed rather than forced, and many times "the play is not worth the candle."

I thought I must train my first baby to good and regular habits. It would be convenient for me, and wholesome for him, if he would go to bed for the night as early as six o'clock, and several times I labored with him two or three hours, in the vain endeavor to make a wide-awake baby go to sleep. A more experienced neighbor taught me better. She remarked, "Perhaps you never can teach that child to go to sleep alone in his crib. I would not try too hard."—"But," I said, "Mrs. Brown's baby goes to sleep in that way, and always has done so."—"All babies are not alike," she said smilingly,

"as I have good reason to know."—She went on to tell me some of her own experience. She supposed that babies must be rocked to sleep, unless they went to sleep while nursing, until she happened once to lay her first child, six weeks old, upon the bed, just as she had put on its night-gown, being suddenly called away to wait upon a neighbor at the door. When she came back to the baby, to her astonishment and admiration, the little thing was fast asleep. Next night she put it in bed awake, and it fell asleep without resistance, and always thereafter did the same, never disturbed unless there was loud talking in the room. This was so charming, the mother thought she would have her next little daughter behave in the same way. But no amount of coaxing or perseverance could reconcile daughter number two to being put to bed awake.

Danger in Trying Too Hard.

Night after night the poor baby screamed and sobbed itself to sleep, almost breaking the heart of its loving and conscientious mother; at the end of a week of such agony, being no more inclined to yield than at first. Then the mother concluded that she had mistaken the path of duty, and gave up the contest, fearing a lasting injury to the darling's health from such excessive excitement.

"Did she conquer you?" I asked.—"I feared so at the time," replied the mother, "but there is not a more obedient child, or a better girl in the world than my Daisy."—I believed her. But, since then, our gentle, conscientious Daisy, in her early womanhood, has suffered from long and dangerous illness, followed by a period of distressing mental weakness and aberration, which was, I have no doubt, connected in the child's vital or nervous history with that week of protracted and severe mental excitement in her baby-hood. Other similar cases have come within my knowledge. We do not know how many of the brightest and best minds have suffered great injury from the conscientious endeavors of their own loving mothers, to train them up in the way they should go. I have heard of one baby who froze its hand one winter night, though it had previously screamed long and loud, because it was an inflexible rule of its parents, not to go near it after it was once tucked up warm for the night in its crib. Mrs. Stowe tells of a baby that pulled the pillow over its face and smothered itself to death, when crying itself to sleep alone.

Going to Bed when Sleepy.

I have had little difficulty with the bed-time business. The little ones go to bed when they get sleepy, and as there is usually an early breakfast to which they like to get up, they are sleepy early in the evening. The bed feels good to a sleepy child, unless mere sleepiness has degenerated into crossness. If a child is half sick as well as sleepy, it probably wants its mother's arms. If little ones are taken arbitrarily away from their playthings or pleasures because "it is bed-time," they learn to regard bed-time as a natural enemy. As a little one's bed-time draws near, the elder members of the family should be considerate, and not propose or introduce new amusements or pleasures, which it will be hard for the little ones to leave. If anything that would have interested the little one happens after it has gone to sleep, it ought not to be mentioned afterward in a way to make the child feel that it has lost something by going to bed early.

Last night, for a wonder, my youngest boy went to bed crying, because he wanted to sit up and see papa. He is seldom awake when his father comes from his work at about seven in the evening, and until quite lately he supposed that papa was only at home a little while in the morning. He was so sleepy he could not keep awake, and finally consented, with tears, to go to bed as usual—only usually he says after a yawn, putting his hand in mine, "I guess I had better go to bed now." I had only just kissed him and wiped away his tears, when I went to the door and saw "papa" coming. I stood there until he came in, and whispered to him to kiss the little one if he was awake enough to notice him, but not to wake him more with play or talk. Behold, the child was already asleep, and then I cautioned all not to tell the baby boy that his papa came as soon as he had gone to bed lest he should

insist still more upon sitting up another time. He has his reward for early retiring, as he is the only child always *sure* of eating a six o'clock breakfast with papa. However the others may lag behind, there he sits in his high chair and bib, holding animated discourse with one who is to his imagination the personification of all the virtues and graces desirable in man.

Cheap Living for Mary and John.

They did get married, it seems; and now Mary inquires of me, how they can economize in the dietetic department to the best advantage of health and general comfort, as well as purse. This Mary has so much natural good sense, that I would not venture to advise her, did I not believe that she will take my advice, or not, just as suits her own judgment. I do not positively know, but I suspect that her John will not be very hard to suit. He has not been greatly pampered in his childhood, and will not think it hardship to live without the dainties, which needlessly consume money and time, and health, in many families. He has not taken enough meals at the best hotels and high-priced restaurants, to give him a hankering for choice porter-house steak, with an expectation that his home cook can give him equally palatable beef-steak, skillfully prepared from any serawny bit of beef, which he can find at the nearest butcher's shop. Economy is absolutely necessary for this young couple, for though John is, as he says, "chock full of day's works," having good health and energy, and industrious habits—we have come to such a pass in this fine and happy land, that many a man, who is willing and eager to work, seems forced to stand idle a part of the time. And then every one should prepare for rainy days ahead.

Meats, Costly and Cheap.

Speaking of meat—the best beefsteaks are extravagant for all but the wealthy. The seeming necessity for more or less beefsteak at breakfast, to give one strength for the duties of the day, is a result of habit. People suppose that it possesses uncommon strengthening power, because it acts so quickly upon the system. A bit of juicy beefsteak yields us nourishment already so nearly assimilated to our own flesh and blood, that we begin almost immediately to feel its help, but many—women and children especially—are over-stimulated by the meat they eat, and receive more harm than benefit from its use. This is a question for individual or family judgment; but when good meat is dear, we may be sure that it is not necessary to the health, if other good food be supplied. In selecting meat, it is by no means cheapest in the end, to "get the best," if this means that which is highest in price. The neck and brisket (breast or breast-piece next to the ribs) are low in price, but long cooking makes them tender and good. A common way now-a-days, and an excellent way, of boiling beef, so as to make it tender, and to save all the juices of the meat, is to "smother it down in the pot," or "roast it in the kettle." Pieces of the leg and shin are also cheap, and from these good soups can be made; and the soup-meat, cut into small bits, or hashed, with or without chopped potatoes, will make good breakfast dishes, warmed with a little butter, salt, and pepper. More than once, one ten-cent soup-bone has helped to make two or three meals at our house, and a fifteen-cent shin-bone has been worked into four meals for six of us—all of which I am not ashamed (as some would be) to confess. Why not brag of it?

Vegetables—Bread.

Vegetables are usually cheap, and good as food. The earliest in market are of course the dearest, but poor folks can wait a little, and enjoy their vegetables just as well, when they have become plenty, and consequently cheap. Potatoes are dear in a time of scarcity, and though I like to see them freely in the family, I do not consider them as necessary as some housekeepers do. Bread is, after all, the staff of life—the best and cheapest food in the end, provided it is good bread. It must be sweet with the natural sweetness of the grain, as well as light and tender. It must contain the bone-building and muscle-making, as well as fat-

producing elements. Good meat (especially beef), good grain (especially wheat), and good milk, each give us all the elements required for the building up and repairing the waste of the human body, yet only milk will do for sole and steady diet, and that only for infants. A "generous diet" embraces a wide variety, and this some of us wish to get with as little expense as possible. We want something to eat with our bread. "Bread and with it," my friend's brother used to say, when in dry times she used to say, "What in the world shall I get for dinner." Concerning the "with it" part, I may write further another time.

Beef Smothered Down.

Two, three, or four hours before dinner, (according to the size of your piece of meat,) put the beef into boiling water, and keep it boiling gently until it is cooked very tender. By this time the water in the kettle should have all boiled away. Season with salt, (and pepper, if you choose,) when the water is mostly boiled away, and turn the meat about in the kettle frequently toward the last. If at any time more water must be added, let it be boiling water. A piece with much bone is not suitable for this method of boiling, as too much water is required to cover it.

Soup Bones.

Any good lean meat may be used for soup, for it is the juice of the meat that is the essential principle of meat soup. But bones contain gelatine, which is chiefly useful in giving body to the soup. Bones, also, contain actual nourishment, according to Dr. Smith, author of "Foods." Those best adapted to soup, are pieces of the leg and shin. They should be well washed, and subjected to a long, steady boiling. So far as the meat is concerned, it need not be boiled longer than until it is cooked tender, which may be in three hours; but the bones do not yield their best contribution to the soup without longer boiling—from six to eight hours, or all day if you like. As poor folks can not afford to give the soup-meat to the dogs and chickens, it is well enough to remove the meat from the kettle when it is done tender, without allowing it to yield all of its goodness to the soup. If you have all of the juice of the meat in the broth and the meat, you can use both as you see fit, without any waste. But if excellent soup is the main object, boil the meat with the bones until all are "in rags," and you can still use the meat. Of course soup-meat must be put into cold water, heated slowly, and boiled very gently, but steadily. I did not mean to tell now all about soup making.

A Neat and Useful Wood-Box.

BY JOS. L. TOWNSEND, PAYSON, U. T.

Wherever wood is burned, as it still is, at least in the kitchen, in many localities, a box of some kind,

Fig. 1.—END VIEW.

to hold the day's supply of fuel, is necessary. Of course a common rough box will answer the purpose, so far as to hold the wood, but if the box, while none the less useful, can be made ornamental also, two ends are gained. Mr. J. L. Townsend, of Utah, sends us very neat drawings of a wood-box of his contrivance, with the following description. "Materials required in construction are: about 30 ft. 1-inch white pine, 6 14-inch No. 8 screws, 1 lb. 6-penny nails, a few brads, and 1 lb. glue. Figure 1 shows an end view with center, from which the circle is drawn at a. Fig. 2 is a front view, from which the ornamental back can easily be reproduced, figures 1 and 2 both being one-sixteenth of the actual size. Figure 3 is a perspective view not

drawn to scale. Size of box, outside measure, 26 in. long, 17 in. wide, 15 in. high in front, and 23 in. high behind to underside of shelf, b. Shelf is 28 in.

Fig. 2.—FRONT VIEW OF WOOD-BOX.

long, and 9 in. wide, moulded on ends and front edge, projecting 1 inch. Ornamental back is cut from a piece 27 1/2 in. long, and 13 1/2 in. wide. At c, figure 3, is shown a drawer, 4 in. deep on face,

Fig. 3.—PERSPECTIVE VIEW OF WOOD-BOX.

sliding under the shelf, b, on cleats fastened to the ends of box, inside. At d is a movable till or box, which rests in place on shelf b, and is secured from slipping off by pins fastened in the shelf, which enter corresponding holes in the ends of the till. Handles to drawer and till are turned from black-walnut, and fastened securely by screws from inside. The box is securely dove-tailed together, front and back, as high as shelf b. The ornamental back-piece is then fastened by dowels and glue in place. The shelf is then nailed on, nailing through the back into the edge of the shelf. The bottom of the box is then nailed on, and the drawer, constructed of the usual pattern, is fitted to its place, so as to slide in and out easily. The till is constructed the same as the drawer, except the front, which is made from 1/4-inch clear, straight-grained pine, steamed, and nailed with 1/4-inch brads, while hot, into its place. I designed and made one which we have now used for three years. It holds enough wood, filled morning and evening, to supply our "Charter Oak" cook stove. The movable till is very convenient to use in gathering chips, or as a receptacle for kindlings. It being as light and portable as a chip-basket, and never in the way. The drawer is used to hold a stove-brush, shovel, blacking, stove-hook, kindling-hatchet, kindling-saw, hearth-broom, etc., being a place for the stove utensils that are usually scattered under foot and out of place. Our wood box is very neatly painted and grained in oak, and combines more usefulness and ornament than any like piece of kitchen furniture in the market. The drawer is not in the way of putting in or taking out fuel, and the boys or men who keep the box supplied, should be taught to place the wood in quietly and regularly, and not to throw it into the box in a careless manner.

BOYS & GIRLS' COLUMNS.

Our Young Microscopists' Club.

SUNDRY THINGS TO DO NOW.

Well, here is more work for "The Doctor"—not that I regard it as "work" exactly, perhaps I might say more fun for "The Doctor." Those of you, and I know that it is several thousands already, who have the *American Agriculturist* Microscope, and have read the Working Description with it, must have noticed that the Publishers have said that "The Doctor" will tell you more about it in various ways. I am very glad to do this, because I am sure that some of you will meet with the same difficulties that I found when I first had a microscope, and I shall be very glad to help you over the hard places. So

OUR YOUNG MICROSCOPISTS' CLUB

consists of all of you who have, or can have the use of, the Microscope sent out by the Publishers. Let me tell you at the start, that this Microscope will not do all, or show all that you have read about as being shown by "the microscope." A "house" may be a log cabin with one room, or it may be a great mansion with 20 rooms, and in each case be a complete house. So this Microscope is very good for one of its kind, costing only a fraction of a dollar, while the one I most use cost \$16, and the one that I use now and then, cost \$50, and if one wishes, he can expend thousands on a microscope. So you see that when one speaks of a "microscope," it is a very indefinite term. The most generally useful microscopes, are not the very costly ones, and the way to begin to use a microscope at all, is to start with a simple and not costly one, and then when you can afford it, get a more powerful one. But my experience—and it has been a long one—has been, that however powerful a microscope one may have—and I have used some of the best that have been made—the little simple microscope, like the *American Agriculturist* Microscope, can not be put aside, as it has uses which the powerful ones can not serve. I am sure that you can learn much from this little instrument, and that it will afford you much interesting amusement for the whole year. Read what is said in the 14 column Description with each Microscope, and at once

MOUNT IT ON A BASE.

The directions there are very plain, and it will take but a few minutes to follow them. You will find that it will make the instrument much more useful and manageable. Then the next most useful thing to do, is to mount some needles as there directed, and to get up some kind of forceps, or tweezers, as there described. Having these and the Microscope mounted as there directed, you will be ready to examine anything that may come along. But one word about

OUR CLUB.

A club has two ends. I am willing to be one end—the handle or the "hitting end," just as you choose—but you youngsters, boys or girls, must be the other end, if you expect the "club" to prosper, you must take a part. Now, you, all of you, boys or girls, or if you like it better, young men and women, must help. How? By writing me what you find, the difficulties you meet with, in short, all about it. Many, no doubt, having read what the most costly microscopes will do, will try to see the same with this—they can't do it any more than they can hit a 1,000-yard target with a pistol. Others will want to know how to prepare things so that they can examine them; and others, still, having found interesting objects, will wish to know how to preserve them, so that they may show them to others, and keep them to look at again and again. So I say to all such, write and tell me all about it. How can I keep up a club all by myself? I shall expect help from all of you—and in turn I will try to help you—Isn't that fair?

WHAT TO LOOK AT.

As soon as spring opens you will find a great abundance of things that you will wish to examine, but just now cold weather puts a stop to animal and vegetable life. The Descriptive Sheet with each Microscope gives a number of things which you may examine with interest—such as flies, spiders, ants, taking separately their wings, legs, proboscis, etc.; fleas and lice on animals, small insects, including the minute lice on plants in the house, dust from the floor and elsewhere; soils, dried and fresh leaves, seeds, feathers, small fish scales, or bits of them, etc. I will give you a few more. One of the great uses of the Microscope will be in helping young people to study plants. Let me give you a starting point in this. Get a piece of one year's growth from any fast-growing tree, say a maple or a willow—any tree that makes strong shoots every year. A piece a few inches long will answer. Then go to the stack of corn-fodder, and get a small stem—no bigger than a lead-pencil is better than larger. Get the smallest stem you can find. Put both of these, the corn stalk and the twig, into warm water, and let them soak for some hours. Now I wish you to

look at a cross section of these, that is, a slice cut across them, to see their structure, that is, how they are made up. To make sections of this kind, there are nice little instruments, which you can get for \$5 or more—but we must do without such expensive things. Having your corn stalk well soaked, and something to cut with—a razor is best, but a very sharp, thin knife may do. Put the corn stalk on a piece of board, put the nail of your fore-finger as a guide, then cut straight down with the razor. This piece will probably be thick; move your nail back the least distance possible, and cut again; this time you may get a very thin slice, but by care, using the nail as a guide, you can soon get a slice as thin as the thinnest paper. It is well to keep the end of the corn-stalk wet, and when you get a nice thin slice, by means of a needle, put it on one of the glass slides of the Microscope. Then try the willow or maple. These are harder than the corn-stalk, and will require more care to get a very thin slice, still, with patience you can do it. Having a thin one, put it by the side of the corn-stalk slice, put the other slide over, and examine

BOTH THE TREE AND THE CORN STALK.

These must be looked at as transparent objects. Having both sections—as these are called—between the two glass slides, push the slides under the clips or springs of

Fig. 1.

Fig. 2.

the Microscope, placing them so that the section of the corn stalk will be in the field of view—that is, directly under the lenses. Having adjusted the focus properly, so that you can see distinctly, the section of corn stalk will appear as in figure 1. Having looked at this carefully, move the slides so that the section of the tree twig is brought into view. Notice that this is quite different, and that it appears as in figure 2. Turn back again to the section of corn stalk, and section of tree, and get them well fixed in your mind. You see how different they are? What is the difference? In the corn stalk you have pith, with dots all through it. In the willow or maple, you have pith in the center, a ring of harder substance, and then a ring of bark. Here in these you have a ring of pith, a ring of woody matter, and a ring of bark. In the corn stalk you have pith, scattered through it dots that look like the woody matter of the tree, and no distinct bark. Now I wish you to look at these carefully, and to recollect distinctly how they look. When you have them well fixed in your mind, slip the sections off from the glasses upon a bit of stiff writing paper, and fold them up carefully, until I can tell you how to preserve them. You have now stems of the

TWO GREAT FORMS OF VEGETATION. The corn stalk stem, in which woody fibre was distributed all through the pith without regular order, and the willow or maple stem, in which the woody fibre was in a ring all around the pith, with a bark outside. Remember this—for it is almost the very beginning of the study of plants. You can try other stems also, and learn to make thin sections. But you will want to be on the lookout for

AMUSING THINGS FOR THE MICROSCOPE, and as we extend over so many degrees and climates, I must keep ahead of the season. In wet places we find, even around New York, very early in the spring, sometimes in March, and those who live in the Southern States, may find it even earlier—the curious Field Horse-tail. With me, it grows in wet sandy places by the roadside, and is one of the first signs of vegetation in spring. In most of the Northern and Middle States, you may look for it in March, if not earlier, and when you find it it will be like figure 3, and of about that size, looking very little like a plant, as it is of a light-brown color, with, at each joint of the stem, a sheath of a darker color.

Fig. 3.

At the top of the stem is an oval head, as seen in the engraving. Later in the season this plant produces green stems—but we do not care about these at present—though we may say that from the pine-like appearance of these stems, the plant is called

GROUND PINE, AND FIELD HORSE-TAIL.

But the stems shown in the engraving are those which appear first, and are the most interesting, though from their strange shape and color they do not look much like plants. I think they must be very common—for I always see them in wet places, as I drive home from the depot, in early spring. If you find these, gather a lot, put them in a bottle, or tumbler, and let them dry. Then, if you wish to see something funny, shake from the heads of these plants some of the dust, which they will give out abundantly, upon one glass slide of your Microscope. It will appear like a ball, with four arms, as in figure 4. While you are looking at it, ask some one to breathe upon it, and you will see a very lively motion; the arms, as if ashamed of themselves, will at once coil around the central portion, and appear as in figure 5. If you wait until the moisture of the breath passes off, the arms will gradually spread out again. What does all this mean? you will ask. The little ball, with the four arms, is to this plant what seeds are to most other plants. This little ball can grow and make a new plant. You can see how the arms, so easily affected by moisture, can, by alternate drying and moistening, move the little seed-like ball to quite a distance. Usually I find a great quantity of this plant close at home, and if I find it abundant this spring, will lay in a lot for those who may want it. And this reminds me that out of our Microscopists' Club—there will somehow grow up

Fig. 4.

Fig. 5.

AN EXCHANGE CLUB.

Those who find interesting things, will wish to send them to others who have things which they want. Well, we shall see what will grow out of it. You may be sure of all possible help from

THE DOCTOR.

Aunt Sue's Chats.

Mrs. T. DAVIS EVANS has been kind enough to send us a description of a home-made frame and corner-bracket. She begins her letter (dated Nov. 24th) with the remark: "As it is about time for Christmas presents, I will try to give you a few hints," etc. It is evident that

Fig. 1.

she did not know (or has forgotten) that six weeks must elapse before my correspondents can receive any acknowledgement through the *American Agriculturist* of their communications. Consequently the Christmas presents for 1877 will be things of the past when this article appears; but things like this are not of necessity

confined to Christmas presents, so her directions are given here, that those who wish may avail themselves of them now, and those who wish to make such presents for next Christmas, will find them on record. I may add that the material is called "corn husks" in the East, and "corn shucks" in the West and South. Each ear of corn is closely surrounded by leafy bodies, which overlap one another, the outer ones being harsh and thick, and often weather-stained, while the inner ones are soft and thin, and of a pleasing color. Mrs. E. says: "First I will describe a shuck picture-frame. Supposing the picture to be 8 by 10 inches, the materials needed are, some nice, white, pliable, inside corn shucks; two pieces of pasteboard (which may be cut from an old box), 12½ inches long by 1½ inch wide, and two pieces 10½ inches long by 1½ inch wide; a coarse needle and strong thread. First sew the pieces of pasteboard squarely at the corners (as in fig. 1).

Fig. 2.

Second, cut a great many shucks about three inches long" (Mrs. E. does not say how wide, but I fancy they might be square.—A. S.), "and shred them as finely as possible (see fig. 2) with a large pin or needle (after a little practice you will find it very easy), leaving at each edge a margin of half an inch unshredded (as in fig. 2). When you have enough to begin with, fold them with the solid edges together (as in fig. 3)—crumpling the

solid part up in the fingers to give them a little fullness, and sew them all along the inner and outer edges of the frame (as in fig. 4), letting them project beyond the paste-board at least half an inch. For the next row cut pieces of the shuck about half an inch wide" (and two inches long?—A. S.), "and fold them into points (as in fig. 5), sewing them on so as to cover the stitches of the first row. (See fig. 6.) For the middle you can either put pieces like the outside rows, only running in the opposite direction (across, see fig. 6), or you can use the points, sewing them on diagonally. As you come to each corner, make a rosette of the shredded shucks, with a piece of solid shuck cut round and

Fig. 3.

gathered to look like a button in the center, as a finish to the rosette. Remember that neither the shredded pieces on the edges nor the points are to be mashed flat.

Fig. 4.—THE SHREDDED PIECES.

"Now for the corner bracket. You need three pieces of thin board, cut in quarters of circles (see fig. 7), each piece a little larger than the last. Say the first is 8 inches from A to C, let the next be 9 inches, and the third piece 10 inches. Bore a hole in each corner for the cord to go through. Cut three pieces of eardboard like figure 8, just long enough to cover the curved side (from B to C) of the board. Cover it with shuck points. Cover the boards smoothly with nice paper. Tack the covered pasteboard (fig. 8) around the curved side of the board;

Fig. 5.—POINTS.

three tacks will be enough, one at each end and one in the middle. Then string the boards on the cord, one at a time, putting a knot in the cord with a little peg through it at the top and bottom of each hole (fig. 9), to keep it from tilting up at one corner and spilling all of the pretty things off. With a little ingenuity, a few collar-boxes, some nice shucks, and bits of silk and worsted, a great many pretty things can be made, such as match-boxes, hair-pin boxes, work-boxes, pin-cushions, jewelry boxes, wall-pockets, watch-cases, etc."... We are much obliged to Mrs. Evans for her instructions in making pretty

Fig. 6.—CORNER OF FRAME COMPLETE.

articles from common materials, and shall be very glad of any other hints she may give us in the fancy-work line.

LEONIE B.—I know nothing about the process of dyeing straw-hats.... I asked a cracker-baker "how to make crackers"; he looked compassionately at me and said it was impossible to make them without machinery. "Why?" I asked.—"Because the dough has to be so stiff that it cannot be manipulated with the hand."—"What are the ingredients used? Flour, water, and salt?"—"Yes, flour, water, and salt; but they cannot be made by hand."—"I suppose we could bang the dough with a cobble-stone rammer! couldn't we?"—"Oh!

Fig. 8.

yes, certainly."—And that was the best I could do for you, Leonie. So suppose you make a very stiff dough of the ingredients mentioned, "manipulate" it with the potato-masher until you have "banged" it quite thin on your paste-board; then cut it into circles about as big as a small saucer; make indentations with a skewer all over them, and bake them; then let me know how they turn out.

MARY E. STAM.—I know nothing about "allspice baskets," but suppose you string the spice upon wire, and weave them into whatever basket shape you choose. "Ethel" signifies "noble," and Ella (the diminutive for Eleanor) "all fruitful."

PHREE-ANN.—You can make a very nice "bandoline" thus: Put a teaspoonful of Gum-Tragacanth into a tumblerful of water to soak; let it stand twenty-four hours, stirring it frequently, and see that it is all completely softened. Gum-Tragacanth is very unlike Gum-Arabic; that dissolves in water, while Tragacanth does not, but it takes up a great deal of water, swells enormously, and forms a thick mucilage. Add water to it, stirring thoroughly, until it is about like thick cream; then thin it with Cologne or lavender-water (the spirit of which will preserve it), until of the consistence for bandoline. [Perhaps every one may not know that Bandoline is the name of a French hair dressing, to stiffen the hair and make it stay in place. It is also made from quince seeds.—ED.]

J. T. F.—Yes, Fall River, Mass., has extensive factories, consuming nearly 140,000 bales of cotton annually, to make about 340,000,000 yards of goods, mostly prints.

Aunt Sue's Puzzle-Box.

As you will all be drawing around the table these cold evenings, I propose to give you another prize puzzle to try your wits and patience over, and to make you better acquainted with the dictionaries. The puzzle is constructed upon the same principle as that given in the April number of the *American Agriculturist*, 1877 (page 147); that is—I have given to each item of the enigma one of the synonyms or definitions given to it in the dictionary. Of course I have selected those that you would be least likely to think of. Which among you thought that—in the last prize enigma—"My 48, 11, 1, 45, 51, 34—chief," meant "staple?" The fact is, we use many words now-a-days, and never stop to consider their meanings. I propose to "stop" you for a minute or two over the accompanying prize enigma. I offer twelve prizes for the first twelve correct answers to it, subject to the conditions undermentioned, which are:—

1st. All answers must reach me on or before the last day of April (1878). 2nd. Answers must be signed with the name and post-office address of the sender, and be enclosed in a sealed envelope superscribed—"Answer to Prize Enigma." This must be put in another envelope, and addressed and mailed to "Aunt Sue, Box 111, P. O., Brooklyn, N. Y." On the first day of May, I will place all the answers received, in a box, and shake them up well. Then—as before—I shall invoke the aid of the little Clara Josephine, who, being then thirty months old, will not be accused of partiality; she shall preside over the box, and shall hand me the answers one at a time. I will open and examine each answer in the order of her selection, and to the first twelve correct answers will accord the prizes, one of which will be mailed, as before, to each winning address. The result will be publicly announced in the July number.

Each prize will consist of a pen and (nickel-plated) holder; the pen shutting into the holder when not in use, and filled with the coloring matter necessary to make ink by simply dipping the pen into water. All the members of one family may work out the solution together, but of course only one member of a family will send an answer. Now get out your dictionary and go to work.

THE PRIZE ENIGMA.

I am composed of 48 letters:

My 44, 9, 32, 2, 5, 18, 40, 48, is to throw out.

My 36, 10, 28, 24, 19, 6, is unbiased.

My 4, 26, 39, 43, 21, is inflated.

My 47, 30, 27, 12, 23, is vital.

My 29, 31, 42, 16, 34, is a charming person.

My 13, 38, 47, 46, 35, 19, is communicative.

My 33, 41, 3, 11, is a countryman,—a rustic.

My 1, 45, 20, 8, 15, is oscillation.

My 25, 22, 7, is a race, a family.

My 14, 17, 37, 5, is to rob.

My whole is a word meaning "shriveled," and part of its definition and application.

ACROSTIC.

1. A city of Holland. 2. A city of New York. 3. A city of Connecticut. 4. A county of Maryland. 5. A town of New York. 6. One of the U. S. capitals. 7. A city of New Jersey. 8. A town of Pennsylvania. 9. A town of Maryland. 10. A city of New York. 11. A town of Iowa. 12. A town of North Carolina. The initials form a good old song.

LITTLE ONE.

DIAMOND PUZZLE.

1. A vowel. 2. To weary. 3. To ensnare. 4. A city. 5. A profession. 6. Joy. 7. To direct. 8. A unit. 9. A consonant. The central letters, read downwards and across, form a profession. NIP.

ANIMALS ENIGMATICALLY EXPRESSED.

1. An engine of war. 2. Tardiness. 3. A small bag. 4. A weight. 5. A city officer. 6. Unfurnished.

FIGURE BLANKS.

Fill the following blanks with some number that will, either in spelling or sound, make sense of the sentence; as—for instance—"1000" in "go ——— ders and call Jim," or—"Go thou Sanders and call Jim.

1. It was my ino ——— ing my ——— der limbs.
2. I ——— eaten any, I am ——— tun ——— in not feeling ill.
3. I never ——— anything at ——— up.
4. It would be well ——— ros ——— use cam ——— and qui ———.
5. I ——— der how you ——— so many.
6. ——— vel was a gr ——— city.
7. By ——— de in adversity men of ——— become ——— n ———.
8. I recommend phy ——— as a gr ——— and thorough study ——— using the mind. JACK SPRATT.

CROSS-WORD.

My first is in scramble but not in push,
My next is in heather but not in bush,
My third is in satchel but not in bag,
My fourth is in horse but not in nag,
My fifth is in house but not in barn,
My sixth is in worsted but not in yarn,
My seventh is in shilling but not in penny,
My eighth is in few but not in many,
My ninth is in true but not in good,
My tenth is in fuel but not in wood.
If from these letters the right you take,
Some very good advice they'll make.

ANSWERS TO PUZZLES IN THE DECEMBER NUMBER.

NUMERICAL ENIGMAS.—1. Beware of reading without thinking of the subject. Up to December 18th, this enigma has been correctly answered by Willie P. Bricker, G. M. Taylor, Cyrene Griffiths, H. M. Innis, Ellsworth W., Mazie Lane, Charles A. Scaver, Bethsinda, C. C. Averill, E. G. Spencer, Mrs. M. H. Dildine, L. M. Hull, W. C. Moore, J. H. Bird, and E. B. Brown.—2. The early bird gets the worm.

CROSS-WORD.—Household.

Pt.—Too late I stayed, forgave the crime,
Unheeded flew the hours,
For noiseless falls the foot of time
That only treads on flowers.

ANAGRAMS.—1. Alternate. 2. Aerimony. 3. Presidential. 4. Lemonade. 5. Purchase. 6. Diameter. 7. Remainder. 8. Negotiate. 9. Remittances. 10. Geometrical.

BLANKS.—1. All, hall. 2. Row, grow. 3. Alter, halter. 4. Lass, glass. 5. Lad, glad. 6. Rove, grove. 7. Lime, elime. 8. Low, flow.

PUZZLE.—(This was—by some mishap—left incomplete by the printer.)

CONCEALED BIRDS.—1. Lark. 2. Wren. 3. Quail. 4. Dove. 5. Grouse. 6. Hen. 7. Swallow. 8. Heron. 9. Teal. 10. Owl.

Thanks for letters, puzzles, etc., to W. Simpers, Minnie Bennett, S. W. A. (M. D.), Isola, Mrs. P. B., Wilbur B. K., Jerry S. S., L. M. H., and Ellsworth W.

Send communications intended for Aunt Sue, to Box 111, P. O., Brooklyn, N. Y., and not to 245 Broadway.

Chimneys and Chimney Sweepers.

We wonder how many youngsters would know the little fellow in the picture if he were not labeled the "Little Chimney Sweeper," and now that they know what he is, can tell much about him? In cities and large towns, when wood was burned altogether, soot, from the wood fires, would collect in the chimneys, and if this were not removed from time to time, it would catch on fire and burn furiously, and if this happened in a dry time, there was danger that the house, or other houses, might be burned. Those who make a trade of clearing out chimneys, are called "chimney sweepers," "chimney sweeps," and more frequently merely "sweeps." A "sweep" is now quite rare in New York, though once in a while we have seen one in the back streets, and looking as if he had not had a job in a very long time. Still, one need not be very old to recollect when the sweep's cry was one of the common street noises. They usually went in pairs, a man and a boy, and as they dressed in keeping with their trade, you may

THE LITTLE CHIMNEY SWEEPER. — Engraved for the American Agriculturist.

be sure that they were not very handsome to look at. They were generally colored people, but if white persons followed the business, they were so blackened with soot, that it was not easy to tell them from the black sweeps. Early in the morning the streets would ring with their cries. The fellows had strong voices, and they would sing rather than shout, "Sweep O. Sweep O. From the bottom to the top, sweep O-o-o-o." But when the people in the cities gave up burning wood, and used coal instead, the trade of the sweeps was spoiled, and their song is now rarely heard—though it is now and then, as there are still a few old-fashioned people who prefer to burn wood—enough in a large city like New York, to give employment to here and there a sweep. The use of coal in place of wood for cooking and warming houses, was a great improvement—and a great blessing too, for if all burned wood now, as they did 50 years ago, it is difficult to see where enough wood could have been found, and it would now be a very costly article. The houses of our grand-parents were, at best, but poorly heated by wood fires, and coal not only brought an increase of comfort, but much labor of sawing, splitting, and bringing in wood and keeping the fire in good order was saved. But the coming in of coal brought a greater blessing than either or all of these—at least to a few—it broke up the trade of the sweeps. You may think it was a blessing to stop them because they were so dirty and noisy, but that is not it. The trade was a bad one, sometimes a wicked one, in the abuse of little

boys. Some machines were invented, which allowed the sweeping of chimneys to be done by men only, but most of the sweeps stuck to the old plan, and had a hoy to climb up on the inside of the chimney, and scrape away the soot from its sides. How many of you boys from six to twelve years old would like such a life as that? Just think how dismal it must have been for these poor little fellows to climb up, at the risk of their lives, the long, black, dark chimney, with the soot filling the air and making it difficult to breathe! But before we say any more about our little friend, the sweep, let us say something about chimneys. You must know that people had fires in their homes long before they had chimneys. How very uncomfortable it must have been to have a fire in the middle of the room, and a hole in the ceiling above for the smoke to go out of, and the rain to come in at. Yet this was the way in which those who, 500 years ago, lived in the grand old castles, managed their fires. We read about the great wealth and splendor of the old barons, with hundreds of followers, but they did not live half so comfortably as the day laborer does now-a-days. The first chimneys were not made like ours: the stone walls of the big houses and castles were very thick, and a fire-place was made in the wall, with a passage in the wall for the smoke, which found its way to the open air through a hole in the side of the building. After a while chimneys, much such as we have now, were built. Where wood is burned, some of the matters that are formed in the burning condense on the sides of the chimney, that

is, they cool and harden there, and this forms what is called *soot*, which in time, would gather in such quantities as to check, if it did not stop the draft. Besides this, as already stated, the soot will burn, and a "chimney on fire," as it is called, is a dangerous affair in a dry time. There were two ways of getting rid of the soot, one was to burn it out; taking a wet day, when there was no danger of setting the roofs on fire. A lot of straw or shavings were put into the chimney and set on fire, and the soot burned out. Another way was to have the chimney swept. Chimneys at first were built very large, but as room became valuable, they were made smaller, and mostly the flues were so small that only a hoy could work his way through them. For many years, in England, the homeless pauper boys were apprenticed to chimney sweeps, and it would be a sad story if the sufferings of these poor little creatures could be told. Living in dirt, and breathing soot, they were subject to peculiar diseases, and one known as the "chimney sweep's cancer," was very fatal. But let us be glad that the law has put a stop to this abuse, and that in England, at least, this wretched use of boys is no longer allowed. Hard, or anthracite, coal is used in all the towns and cities on the Atlantic coast; this makes no soot, but where the soft or bituminous coal is used, as it is west of the Alleghenies and in Europe, the chimneys get foul and must be swept. There is, however, no more need of employing boys to scrape the chimneys, as there are now contrivances by which the sweeping may be done without them.

[ADVERTISEMENTS.]

The gentlemen representing the New England Silver Plate Co., of New Haven, Conn., are reliable and trustworthy, and the readers of the *Agriculturist* will find themselves well rewarded for any money they may invest in their goods. They have two advertisements in this issue, one on this page and one on page 77, both of which are very readable and tasty.

IMPERIAL EGG FOOD.—This valuable article for making hens lay, is endorsed by the *Poultry World*, excellent authority, as being "by odds the best thing of its kind ever gotten up on either side of the ocean," while Geo. P. Burnham, the veteran poultry breeder and author says: "Imperial Egg Food has wonderful properties in increasing the production of eggs."

One week's trial of it in your poultry yard, will convince the most incredulous of its value. See advertisement on page 76.

H. N. SQUIRES, 37 Fulton St., N. Y. City.

Pure Gum RUBBER BOOTS!

Will Outwear Common Rubber Boots.

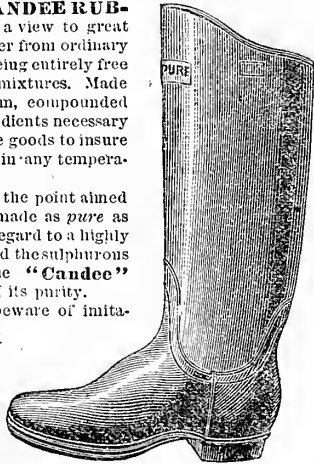

Made by the "**CANDEE RUBBER CO.**" with a view to great durability, and differ from ordinary Rubber Boots in being entirely free from adulterative mixtures. Made of Pure Para Gum, compounded only with the ingredients necessary to "vulcanize" the goods to insure uniform pliability in any temperature.

Durability being the point aimed at, the Boots are made as pure as possible, without regard to a highly finished surface, and the sulphurous appearance of the "**Candee**" Boot is evidence of its purity.

Buyers should beware of imitations, as "dull finish" Boots of cheap quality are on the market and are sold to the unwary for "Pure Boots." All Pure Boots are branded thus:

"STANDARD PURE,
L. CANDEE & CO."

No orders received at Factory. Ask your dealer for the "**Candee**" Boot.

H. W. JOHNS PATENT ASBESTOS PAINTS

These Paints are in every respect *strictly first class*, and second to no others in the market in purity, richness, and permanency of color, beauty of finish, and durability. They are prepared ready for the brush, in twelve newest shades, and standard colors, suitable for the tasteful decoration of all classes of buildings, inside and out, and for all purposes where a perfect protective coating is required.

They contain no water, alkali, or other useless or deleterious ingredients, such as are used in nearly all the liquid or so-called chemical paints, and are guaranteed to be the most durable paints in the world for exposed wood and iron work.

Owing to the wonderful covering properties of these Paints, the farmer, merchant, and manufacturer can, by their use, preserve and beautify their buildings, fences, or other wood and iron work, at from one-half to two-thirds of the usual cost of other ready mixed paints, or white lead and linseed oil. These Paints are sold by standard U. S. gallon measure, and our packages contain from eight to twelve per cent more paint than those usually sold.

ASBESTOS ROOF PAINT, for tin and shingle roofs, iron-work, agricultural implements, fences, out-buildings, etc. We guarantee this to be a better article than has ever before been offered to the public for similar purposes.

SOLID SILVER TEA SPOONS, AT MANUFACTURER'S COST PRICES,

Is what we can supply the readers of this paper, if desired, at a price as low as any jeweler pays for them at wholesale. We will mail on receipt of price, one set of six **SOLID Silver Tea Spoons** for \$3.50, (cost at retail from \$6 to \$7), or, for 85 cents, which covers the cost of the spoons, as well as postage and packing, we will send by mail or express, prepaid,

ONE SET OF 6 QUADRUPLE TEA SPOONS IN CASE, finely and heavily plated with **PURE NICKEL**, and **COIN SILVER**, on a new metal, called **Alfenide**, which is very similar to the finest English white steel. It contains no brass or German silver in its composition, and consequently no poison, or disagreeable taste. Are very strong and will wear for years. Two sets, \$1.50.

We shall not furnish these goods to the trade, consequently they cannot be supplied by any other manufacturer or dealer.

We also make of same quality, Table Spoons 6 for \$1.75; Forks, 6 for \$1.75; Table Knives, balanced, solid steel handle and blade, triple plate, 6 for \$2. **New England Silver Plate Co., Man'rs. New Haven, Ct.**

Pringle's New Hybrid Spring Wheats.

\$250

IN PREMIUMS

\$250

IN PREMIUMS

We take much pleasure in announcing two new and distinct varieties of **Spring Wheat**, produced in 1870 and 1871 by Mr. Pringle, of Vermont, whose skill and judgment as a hybridizer of Cereals and Potatoes have already won for him a world-wide reputation. After a careful trial of six years, we now offer these varieties to the public, having entire confidence in their superiority over all others, feeling assured that they will prove to be valuable acquisitions to the wheat growers of the country.

CHAMPLAIN.—A bearded variety—a cross between the Black Sea and Golden Drop—combining the remarkable hardness of the former, with the superior quality of the latter. Its strong and vigorous straw, growing 6 to 12 inches higher than its parent varieties, stands erect, frequently bearing even in very ordinary culture heads from 5 to 6 inches in length, containing from 60 to 75 kernels each.

Price, \$1.00 per lb.; 3 lbs. \$2.50, by mail, post-paid.

DEFIANCE.—Another variety of Spring Wheat of the highest promise, of which the above cut is a fair representation, the result of a series of experiments, to incorporate superior qualities upon the hardy stock of our common Club Wheat, by hybridizing it with one of the finest, whitest, and most extensively grown sorts of the Pacific Coast.

This variety displays great productiveness, vigor, and hardness. It is a beardless, white chaff wheat, with heads frequently 5 to 6 inches long, very closely set with large white kernels, frequently numbering 75 to 80 to the single head.

Price, \$1 per lb.; 3 lbs. \$2.50, by mail, post-paid.

In order to induce Wheat Growers to give these new sorts a thorough and universal trial, we offer **\$250 in premiums** for the largest quantities grown from 1 pound of seed, also for the 20 largest heads. For particulars see Circular.

EARLIEST TOMATOES KNOWN, BLISS' LITTLE GEM.

Numerous testimonials received from those who tested this variety the past season, pronounce it two to three weeks earlier than any other variety. At the great Tomato Trial in London, at the Horticultural Society's gardens, it was the earliest of 60 varieties on trial, and received a first-class certificate. 15 cts. per packet.

ACME.

This new and beautiful variety is one of the finest ever produced. Its rosy-purple, glossy skin, fine symmetrical form, and delicious flavor, render it worthy of general cultivation. It is also a very early variety, surpassing all others in this respect, excepting the "Little Gem." 15 cts. per pkt.; 1/2 ounce pkts., 75 cts.

A Descriptive List of our Novelties for 1873, with particulars respecting our Offer of Premiums in Wheat, will be mailed free to all applicants.

Address **B. K. BLISS & SONS, 34 Barclay Street, New York. P. O. Box, 5712.**

Fine shade trees. Full particulars in ALBANY, N. Y., COUNTRY GENTLEMAN of Dec. 20, Jan. 17 and 24, or address SARAH H. DE COU, Executrix, Yardville, Mercer Co., New Jersey.

AMERICAN AGRICULTURIST.

ORANGE JUDD COMPANY, Publishers, 245 Broadway, N. Y.
ANNUAL SUBSCRIPTION TERMS (always in advance):
\$1.60 each for single copies: Four copies, \$1.30 each: Ten
copies, \$1.20 each: Twenty copies and upward, \$1.10 each.
These rates include Postage, in each case, which is pre-paid
by the Publishers. Papers are addressed to each name.

The full Descriptions and Illustrations of the Premiums, with various Notes and Explanations, were published in 8 extra pages of our October number, which can not be repeated for want of space. Any one not having that number, can have one mailed, post-paid, for 10 cents; or a Premium Sheet only, will be mailed to any address without charge.

PREMIUM

Explanatory Notes.

N. B.

Read and carefully Note the following Items: The Table herewith tells the name and cash price of each article, and (in last column but one), gives the number of names sent in at the regular price of \$1.60 a year that will secure any premium article. (The last column gives the number of names at the lowest club price for 20 or more names, that is \$1.10 each, but only a part of the premiums come under this head. Some persons quickly raise large clubs by taking all the names at \$1.10 each, and themselves pay the difference, 50 cents each, and even thus get the premium articles very cheaply.)... (a) All subscribers sent by one person count, though from several different Post-offices. But... (b) Tell us with each name or list of names sent, that it is for a premium.... (c) Send the names as fast as obtained, that the subscribers may begin to receive the paper at once. Any one can have any time desired, up to next July, to complete any list, but every premium desired will be sent as soon as earned and ordered.... (d) Send the exact money with each list of names, so that there may be no confusion of money accounts.... (e) Old and new subscribers all count in premium clubs, but a portion at least should be new names; it is partly to get these that we offer premiums to canvassers.... (f) One or two Specimen Numbers, etc., will be supplied free, as needed by canvassers, (when 3 cents per copy is furnished to pre-pay postage), but they are expensive, and should be used carefully and economically, and where they will tell. Other specimen numbers will be sent, post-paid, to canvassers only, for 10 cents each. The price to others is 15 cents.... (g) Remit money in Checks on New York Banks or Bankers, payable to order of Orange Judd Company, or send Post-office Money Orders. If neither of these is obtainable, Register Money Letters, affixing stamps both for the postage and registry; put in the money and seal the letter in the presence of the Post-master, and take his receipt for it. Money sent in any of the above ways is at our risk; otherwise it is not.

Premium Articles for Sale.

It often happens that persons, who have not time to secure these valuable and useful premium articles by raising clubs of subscribers, are desirous of purchasing one or more of them, and wish us to procure or select them. For the accommodation of such, we will supply and send most of these premiums for cash, at the prices in the Descriptive List, and prepaid or otherwise, as stated.

Table of Premiums

For Subscribers to American Agriculturist.

[In the following table is given the price of each article, and the number of subscribers required to get it free, at the regular rates of \$1.60 a year, and also (with a part of the premiums), at the club rates of \$1.10 a year, postage included, which is prepaid in all cases by the Publishers.]

TABLE of Premiums and Terms

For Volume 37—(1878).

Open to All—No Competition.

No.	Names of Premium Articles.	Price of Premiums.	Number of Subscribers required at or above \$1.60 1.10
1	Tea Set (Middletown Plate Co.)	\$50 00	66
2	Ice Pitcher (do. do. do.)	\$13 00	20
3	Cake Basket (do. do. do.)	\$7 50	16
4	Cake Basket (do. do. do.)	\$10 00	18
5	Casters (do. do. do.)	\$5 25	13
6	Casters (do. do. do.)	\$7 50	16
7	Casters (do. do. do.)	\$10 50	19
8	Butter Cooler (do. do. do.)	\$6 50	15
9	Pickle Jar and Fork (do.)	\$5 00	12
10	Syrup Cup with plate (do.)	\$6 25	15
11	Child's Cup (do.)	\$3 50	8
12	Twelve Teaspoons (Meriden Cutlery Co.)	\$7 25	16
13	One Dozen Tablespoons (do. do.)	\$14 50	22
14	One Dozen Table Forks (do. do.)	\$14 50	22
15	Ladies' Folding Pocket Scissors (do.)	\$1 50	4
16	Child's Knife, Fork & Spoon (do.)	\$3 00	8
17	French Cook's Knife, Fork, & Steel (do.)	\$3 75	9
18	Set of Scissors (C. S. Steel Shear Co.)	\$4 00	10
19	Portable Writing Desk (C. W. F. Dore)	\$7 50	14
20	Walnut Work Box (do.)	\$1 25	4
21	Buck-Saw for Boys (do.)	\$1 50	4
22	Little Girl's Wash Set (do.)	\$1 00	3
23	Sled (do.)	\$2 00	5
24	Spring Horse (do.)	\$11 00	18
25	Boy's Wagon (C. W. F. Dore)	\$5 00	12
26	Boy's Tool Chest (E. J. Horvath)	\$1 00	3
27	Boy's Larger Tool Chest (do.)	\$2 50	7
28	Boy's Larger Tool Chest (do.)	\$5 00	12
29	Pat. Magic Belthead Pencil (Ludden & Taylor)	\$1 50	4
30	Ladies' Magic Charm Pencil (do. do.)	\$2 00	5
31	Gents' Magic Charm Pencil (do. do.)	\$2 75	7
32	Gold Pen, Telescope Case (do. do.)	\$2 50	7
33	Gold Pen and Pencil, Elegant (do. do.)	\$5 50	13
34	Knives and Forks (Patterson Bros.)	\$14 75	22
35	Knives and Forks (do. do.)	\$18 50	28
36	Carver and Fork (do. do.)	\$3 75	9
37	Pocket Knife (Meriden Cutlery Co.)	\$1 50	4
38	Pocket Knife (do. do.)	\$2 00	5
39	Pocket Knife (do. do.)	\$2 75	7
40	Ladies' Pocket Knife (do. do.)	\$2 00	5
41	Multum in Parvo Knife (do. do.)	\$3 50	8
42	Crandall's "John Gilpin" (do.)	\$1 00	3
43	Crandall's "District School" (do.)	\$1 00	3
44	Crandall's "Masquerade Blocks" (do.)	\$1 00	3
45	Crandall's "Acrobats" (do.)	\$1 00	3
46	Crandall's Building Blocks (do.)	\$1 50	4
47	Crandall's "McNaghtie" (do.)	\$2 00	5
48	Pair of Skates (Patterson Bros.)	\$3 50	8
49	Boudoir Clock (S. B. Jerome & Co.)	\$3 50	8
50	Wire Bed Mattress (H. Buckingham)	\$12 00	19
51	Houck's Patent Pocket Cook Stove	\$1 35	4
52	Houck's Press (W. A. Doanman)	\$2 00	5
53	Aquapult (Force Pump) (W. & B. Douglas, Middletown, Conn.)	\$9 00	17
54	Self-adjusting Gold-plate Watch Key, (J. S. Birch)	\$1 00	3
55	Pocket Tool Holder (Miller's Falls Co.)	\$1 00	3
56	Piano, Splendid 7-Oct. (Steinway & Son)	\$650 00	625
57	W. S. Hunt's "Universal Force Pump"	\$12 00	19
58	Water Watch (American Watch Co.)	\$50 00	44
59	Bracket Saw (Miller's Falls Man'g Co.)	\$1 25	4
60	Payson's Indelible Ink—Pen, etc.	75	3
61	Excelsior Pocket Microscope (Bausch & Lomb Optical Co.)	\$2 75	7
62	Abbott Pocket Microscope (L. G. Abbott)	\$1 50	4
63	Cahoon's Broadcast Seed-sower	\$5 00	12
64	Moore's Floral Set (Moore Man'g Co.)	\$1 00	3
65	Garden Seeds & Flower Dubs (select)	\$2 00	5
66	Planet Jr. Combined Drill & Hoe (S. L. Allen & Co.)	\$12 00	19
67	Breech-loading Pocket Rifle (Stevens)	\$16 00	24
68	Double Barreled Breech-loading Gun	\$50 00	66
69	Shot Gun (E. Remington & Sons)	\$6 00	14
70	Shot Gun, breech-loader (do. do.)	\$23 00	36
71	Creedmoor Long Range Rifle No. 1 (do.)	\$100 00	110
72	Creedmoor Long Range Rifle No. 2 (do.)	\$55 00	100
73	Creedmoor Long Range Rifle No. 3 (do.)	\$60 00	75
74	Hunting & Target Rifle (Remington)	\$22 00	84
75	Vest Pocket Pistol (Remington)	\$3 75	9
76	Revolver (Remington)	\$9 00	17
77	Turn-table Apple Parer (Goodell Co.)	\$1 00	3
78	Chinaz Apple Corer & Slicer (do.)	\$1 00	3
79	Family Cherry Stoner (do.)	\$1 00	3
80	Bay State Apple Parer & Slicer (do.)	\$1 50	4
81	"Saratoga" Potato Peeler & Slicer (do.)	\$1 00	3
82	Sewing Machine (Remington)	\$50 00	66
83	Family Scales (Fairbanks & Co.)	\$14 00	21
84	Clothes Wringer (Best—Universal)	\$8 00	16
85	Worcester's Great Illustrated Dictionary	\$10 00	18
86	Any back Volume Agriculturist	\$1 75	20
87	Any Two Back Volumes do.	\$3 50	35
88	Any Three do. do. do.	\$5 25	13
89	Any Four do. do. do.	\$7 00	15
90	Any Five do. do. do.	\$8 75	17
91	Twenty-one Vols. XVI to XXXVII	\$56 75	58
92	Any Back Vol. Agriculturist	\$2 00	25
93	Any Two Back Volumes do.	\$4 00	46
94	Any Three do. do. do.	\$6 00	15
95	Any Four do. do. do.	\$9 20	17
96	Any Five do. do. do.	\$11 50	19
97	(Each ad'l volume at same rate)		
97	Twenty-one Vols. XVI to XXXVII	\$48 80	66
98	A \$10 Library (your choice)	\$10 00	18
99	A \$15 Library do.	\$15 00	24
100	A \$20 Library do.	\$20 00	31
101	A \$25 Library do.	\$25 00	38
102	A Choice of Good Books. (See Description, p. 408.)		

Every Premium article is new and of the very best manufacture. No charge is made for packing or boxing any article in our Premium List. The Premiums, Nos. 15, 18, 29 to 33, 37 to 41, 49, 51, 54, 55, 59 to 62, 65, 75, 76, 86 to 102, inclusive, will each be delivered FREE of all charges, by mail or express (at the Post-office or express office nearest the recipient) to any place in the United States or Territories.—The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance desired. Illustrated and Descriptive List sent free to applicants.

containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from p. 49.

Doubling the Crop of Strawberries.—"A. C." has seen it stated "that 1 lb. nitre, and 1 lb. ammonia dissolved in 1 hogshead of water, and sprinkled on the strawberries, will double the crop," and asks how much truth there is in the above. We suppose that the liquid is to be sprinkled over the vines rather than the berries, but in either case it would be of no use, as to be of any service the application should be made to the soil. Nitre (nitrate of potash or saltpetre) and ammonia, either or both, are good fertilizers for the strawberry, but we get any good results that may be expected from these, by the use of guano, or guano and ashes, both being excellent fertilizers for the strawberry. The reason A. C. has not seen ammonia (pure or uncombined) offered as a fertilizer, is because it is properly a gas, and can only be kept in a manageable state when dissolved in water, as the Water of Ammonia, or Spirits of Hartshorn. It is most conveniently applied in the form of the sulphate, and Sulphate of Ammonia is a regular article of trade with the dealers in fertilizers.

Gate to Prevent a Back Flow of Water.—"C. G.," Dardanelles, Arkansas. To prevent the reflux of water from a river into a creek during high water, it will be necessary to embank the creek for a sufficient height, and to put in a self-acting gate, that will open only outwards to let the creek water out. When the river rises, the pressure of the back water will close the gate, and keep it shut until the low level is restored.

Stables for 75 Sheep.—"J. B. S.," Johnstown, Pa. In the American Agriculturist for Aug., 1874, we gave illustrations and descriptions of a sheep barn, which would accommodate 75 or more sheep. This number can be procured for 15 cents. Several plans for sheep sheds or barns are given in Stewart's "Shepherds' Manual," price \$1.50.

Mr. Vick, Please Stop Growling!—James Vick—perhaps our readers may have heard of him—sells seeds and things in Rochester, N. Y. He has a grievance. Foreigners can send their seeds through Uncle Sam's mails for four cents a pound, while Americans have to pay sixteen cents a pound. Vick, it serves you right, you shouldn't be an American. Why don't you be as acute as the Detroit dealers? All they have to do is to run their stuff across the river to Windsor, and they can avail themselves of superior mail advantages just as well as if they were foreigners. We should think that a man of your enterprise would run a steamer from Charlotte, (we think that is the name of that very sandy and white-fishy place close by you on the lake), over to the other side, where no discriminations are made against a man just because he happens to be a citizen of the United States. Vick, please don't be unreasonable. What's a paltry twelve cents a pound, on the few dozen of tons you send out annually, compared with being able to sing "My Country 'Tis of Thee."

The Atlantic Monthly.—Each of the several monthly magazines has its peculiar features, which make it acceptable to its circle of readers. To say that the "Atlantic" caters to the taste of the most highly cultivated portion of the community is to repeat what every one knows. Its monthly issues are always fresh, with articles that live beyond the month, and its list of contributors includes well nigh all the names of our best writers. The prospectus for 1878 is very attractive in the names of those who are to contribute to the volume, but the publishers need only to say that the Monthly will be kept up to its own high standard, and its readers will be content. The publishers of the "Atlantic," H. O. Houghton & Co., Boston, have issued superb life-size portraits of the poets Bryant, Longfellow, and (recently) Whittier, either of which is sent for a dollar added to the subscription price.

Composting Muck with Ashes.—"A. L. W.," Kittery, Me. Twenty-five cents is too much to pay for leached ashes. They should not be worth more than half that amount in any part of Maine. Freshly burned lime at 10 cents a bushel would be preferable for the purpose. Two bushels of lime to a cord of muck would make a good compost. The lime should be air slacked and fine before it is mixed with the muck.

Herding Cattle for Fun.—"E. R. H.," Huntington Co., Pa. It is a great mistake to suppose that there is any fun in herding cattle on the Plains. On the contrary, it is one of the hardest and most dangerous of employments. Stockmen there do not want to hire inexperienced men, simply to give them opportunities for horse riding or sight seeing. To get employment on a cattle ranch, a man needs experience which has been gained through work and exposure that would kill a dozen young men who have lived in a city, and fancy they would find pleasure in the occupation. If there is any pleasant share in the business, it is that of the owners who have invested large sums in it, and can afford to take things easy while their hired men do the work.

Good Eyes and Steady Nerves are those of E. Eastman, of North Flavelhill, N. H., who, in sending for the *American Agriculturist*, at the age of 75, does it in penmanship that is really beautiful. Besides this, he sends a specimen of what he can do if he tries. Within the space of $\frac{1}{8}$ an inch long, and $\frac{3}{8}$ wide, he writes the Lord's Prayer, and without the aid of glasses; though it can not easily be read without a magnifier. A wonderful performance at any age, but at 75, it is astonishing. Mr. E. attributes this extraordinary preservation of his faculties to abstinence, during a life passed in agricultural pursuits, from strong drinks and tobacco.

"St. Nicholas," an illustrated magazine for girls and boys. It is edited by Mrs. Mary Mapes Dodge, and published monthly by Scribner & Co., N. Y., and when we say that there is not in the whole world anything of its kind that can touch it with a 10 (thousand) foot pole, it may be inferred that we think "St. Nicholas" will do. Mrs. Dodge is to be congratulated on having such publishers, and the publishers should rejoice that they have such an editor.

Subjects for Discussion at a Farmers' Club.—The following list includes the subjects to be brought up for discussion at the meetings of the Concord (Mass.) Farmers' Club, viz.: "What have we farmers learned the past year?...History, Culture, and Uses of Indian Corn....Production and Application of Manure....Can we Afford to Raise Our Stock?...Root Crops....How Farming Pays Best....How Shall we best Utilize our Hay?...Value of Experiment Stations....Cross Fertilization....Systems of Cultivation and Production....Insects Injurious to Vegetation....Are our Seasons becoming Drier?...Supply and Demand....Healthy Houses....Exhaustion of the Soil....Poultry Breeding....In and in Breeding....Opportunities for Young Farmers"....This list may be useful to other clubs, both in suggesting a choice of subjects, and as an example of some questions which can hardly be profitably discussed, being insoluble and only resulting in irreconcilable differences of opinion at the best.

Proposed Amendment of the Patent Laws.—A bill has been introduced into Congress for the protection of farmers against suits for the involuntary infringement of patent rights, by the use of machines, implements, or articles which are claimed to be illegally made or sold. It provides that no suit can be enforced against an innocent purchaser, nor unless it can be shown that the purchaser was aware of the infringement at the time of the purchase. This is a very important and much needed measure, in view of the innumerable conflicting claims as to the patent rights on chains, gates, fences, barbed fences, lightning-rods, and the scores of other things which are peddled all over the country by seductive and irrepressible agents, who sell something only to be followed by another sharper, claiming a fee for the use of what the first man sold.

The "Gardener's Monthly."—The *Variegated Grape*.—With the December number, our able horticultural cotemporary closes its 19th volume. In these 19 years it has seen a number of other journals retire from the field; notably "The Horticulturist," founded by A. J. Downing, which fell into hands that so starved it that it was almost too weak from inanition to stand up and be swallowed by the "Gardener's Monthly." Then there was a Boston journal—we have quite forgotten its name—that started out, ignoring all things that were, or had been, in horticulture, and looked with contempt upon the slow-going "Gardener's Monthly." The most highly inflated balloon, if let alone, will, by a well known law of endosmosis, gradually diffuse its gas, and collapse. This is what happened to the Boston journal. We are glad to see that the "Gardener's Monthly" closes its volume with many signs of prosperity, among which we count an excellent colored plate of the *Variegated Grape*, *Vitis heterophylla*, which, under various names, including *Vitis variegata*, *Vitis humulifolia*, *Ampelopsis tricolor*, *Cissus quinquefolia variegata*, and others, has been in our nurseries for several years. It does not seem to have become so

generally known as its merits deserve. Its handsomely lobed leaves are abundantly splashed and blotched with light green and white; the stems of the young growth, leaf-stalks, and stalks of the fruit-clusters, are light crimson, and the abundant berries, about the size of peas, take on in autumn the richest of blues. The plant is seen at its best in a partially shaded place, as in full sun its variegations are less marked. It may be used to cover a trellis, or if grown to a stake, it will form an irregular mass of great beauty, especially when in fruit.

Prize Essay on Diseases of Swine.—The American Berkshire Association has issued in pamphlet form the \$100 prize essay on diseases of swine. This essay, with 500 pages, containing 1,600 pedigrees of swine, are given in the second volume of the Berkshire Record. The price of this volume is \$5. The essay by itself is sold for twenty-five cents. The Secretary of the Association is P. M. Springer, Springfield, Ill.

To Destroy Dewberries.—"Geo. G. P." W. Sulphur Springs, W. Va. It is a difficult matter to destroy the variety of creeping blackberry known as dewberries. Every piece of root left in the ground will make a new plant. We once freed a field from this pest by deep plowing, so as to turn up all the roots and then thorough harrowing and cultivating to tear them out of the ground. The roots were then gathered and burned. The ground was planted to corn, cultivated flat, and sown to clover at the last working of the corn. No dewberries appeared after that. Lime and manure only affect them by encouraging the growth of the crop which smother them out. Sheep will consume them, when there is nothing else to eat.

A Great Improvement in Plows.—If we could prevent the points of our plow-shares from wearing out, it would be a very great economy in preserving the shares. The New York Plow Company has adapted a new device of a movable and reversible slip point for the shares of their adamant plows. This point,

when worn on the under side, is taken out and reversed; and when worn out a new one is put in; thus the share will wear a very long time without needing to be replaced. The engraving here given shows the form of the slip-point and share. The point is keyed on with a piece of 10-penny nail. The improvement, although quite new, has already taken prizes at the New York State, and Queens Co., (N. Y.), and New Jersey State Fairs.

A Plan to Find the Seat of Inflammation.—"Farmer," recommends persons who have horses that are suffering from inflammation in the joints or muscles, to apply cold water to the suspected parts; the seat of the trouble will be found where the moisture dries off the most quickly.

Baling Manure.—"H. T. R.," Montgomery Co., Pa. We can not give you the present address of the patentee of the process for baling manure. We suppose, from the fact that we see no notices of this process made public, that the patentee has no desire to give any information respecting it.

Size of House for Fifty Hens.—"F. H. C.," Freeport, Me. A house 10 feet wide, 15 feet long, and 8 feet high, is large enough for fifty hens.

The Shorthorn Convention.—At the Shorthorn Convention, held at Lexington, Ky., Oct. 31st, the most noteworthy proceedings was a report by a vote of 30 to 9 to admit native bred animals having six crosses. Others that trace back to imported sires and dams are admissible with six crosses; a resolution to the effect that color in this breed is immaterial, and that the popular desire for red animals is injurious to the Shorthorn interest; also, the recommendation that

animals desired to be milkers should be bred early, while beef cattle should be matured before being bred. An evident impression prevailed that the milking capacity of Shorthorn cows should be encouraged.

Grass for Wet Meadow and Timber land.—"A. B. T.," Nora Springs, Iowa. Timothy and red top mixed at the rate of a peck of the first and a bushel of the latter per acre, would do well upon a moist drained meadow. Orchard grass and Kentucky blue grass, a bushel of each per acre, would be the best for open timber land.

How to Use Bones as a Fertilizer.—"L. R. S.," Bridgewater, N. Y. The easiest manner of preparing bones for use, is to burn them with wood. The phosphate of lime is all in the ashes, but the nitrogen is lost, as the animal matter is burned away. But an equivalent of ammonia could be purchased in the shape of dried blood, meat, or fish guano, for less money than it would cost to reduce the bones to a fine powder in their raw condition. 100 pounds of dry bones contain 45 pounds of gelatine, in which there are about 5 pounds of ammonia. This could be replaced by 20 pounds of sulphate of ammonia, at a cost of $\frac{5}{8}$ cents per lb., or \$1.10. As the sulphate is at once available, while the ammonia of bones is only slowly produced, half or a fourth of the former would supply an equivalent of the bones.

City Manure or Artificial Fertilizer.—"J. C. L.," Philadelphia. We would rather use some good artificial fertilizer, such as Peruvian guano, or any of the prepared special manures, than city manure at a dollar a cartload. 100 lbs. guano per acre in autumn, would be very effective, and if repeated in the spring, would be of more use, than the same value in city manure, were it of better quality, than it usually is.

Renting Farms.—"Homestead," Indiana. We certainly advocate the renting of farms by young men, who have not sufficient capital to purchase land. The ownership of land is by no means necessary to success in farming; on the contrary, there are thousands of farmers who would be better off if they had some money in their possession to stock a rented farm, rather than own some land which they have not means to cultivate. Money invested in land is well called *real estate*, because there is no possession surer than a piece of land that is paid for. But as a compensation for perfect security, the interest derived from an investment should be low. No farmer can, or should, afford to pay more than four per cent on the value of land, as rental. Interest has been, and is, too high for the farmer's profit. If farms can be rented for this rate, it would pay many now owning land to rent instead. Money used in fluctuating business, such as the cultivation of land, ought to pay from 10 to 20 per cent. Every good farmer should be able to make that profit from his working capital; that is, live stock, tools, seed, and fertilizers. Therefore, one who rents his land, provided he has a long and secure lease at a reasonable rate, should make more money in proportion to his capital, than he who owns his land. Every farmer *should*, if he can, own his own farm, and have sufficient capital to work it; but as this is impossible, then let those who cannot do both, rent farms and use sufficient capital to work them thoroughly and profitably.

Packing Eggs in Salt.—"D. H. S.," Landsburg, Pa. Eggs can not be kept very long when packed in salt. The preserving process must necessarily render the shells impervious to air, else the eggs gradually decay. There is no better preservative than linseed oil smeared over the shells, or immersing them in milk of lime, which has been described so frequently.

Questions about Eggs and Fowls.—"A. G. O. M.," Manitoba. We do not believe half the reports current about extraordinary production of eggs. Yet it may easily be true that a hen of the non-sitting breeds may lay an egg every day for a long period. The Black Spanish hens often do this, and we have personally known one to lay two eggs in one day, but there was none the next day. Hens can not well cover goose eggs and keep them warm, they are too large. If the bottom of the nest is made warm with down or feathers, a hen may possibly keep six of these eggs warm enough. A young bird needs no help to get out of the shell, unless it is very weak, in which case it is about as well for it to remain there, as it would probably fail to thrive. If the chicks should need any help, this can be very easily given when an incubator is used. Light Brahma chicks, when newly hatched, are all white; Dark Brahmas are black and brown; Plymouth Rocks are black and yellow, and Black-red Games are black and yellow, or brownish.

"Currants" and Sultan Raisins.—Our common currants, got their name from some resemblance to the fruit imported into England long ago

from Corinth. These were called "corinths," whence the name currant. The dried fruit sold in the stores as currants, are really small seedless grapes. A correspondent in a recent "Gardener's Chronicle" gives an interesting account of their culture. It appears that their production is confined to a limited district on the Gulf of Patras, and that the vines taken elsewhere are so apt to produce fruit with seeds, that their culture can not be general in other localities. The vines are trained to stakes, until strong enough, to support themselves, and found to yield, when in full bearing, from 50 to 90 bunches each. The best growers place the gathered bunches in trays, 6x3 feet, exposed to the sun. Should a rain come, the trays are stacked in piles, with a temporary roof to protect them. The fruit falls from the bunches in about six days, and the drying is completed in about six days more. The average yield is about 25 cwt. per acre, valued at the place of export at about \$100 per ton. The Sultana raisins are from another seedless grape, and their culture restricted to the hills about Smyrna. The clusters, when picked, are dipped in ley to which a little olive-oil is added; this is thought to facilitate the drying. The export of currants from Greece in 1876 was 86,500 tons, and that of Sultanas is about 10,000 tons annually.

The Attar or Otto of Roses.—The war in Turkey not only interrupts the production of wheat and other articles of food, but also that of luxuries. The district of Kezanlik is the principal source of what is known as Attar or Otto of Roses, which is properly the Oil of Roses, the others being Turkish names meaning perfume. According to a correspondent of the London "Times," the passage of the armies has left hardly a house or a crop standing in the whole region, and those who indulge in the usually costly and much adulterated perfume, will have to pay still more for it. The roses are cultivated in hedges, and the flowers collected before sunrise, are placed in a rude copper still with water, heat applied, and the water that distills is collected; after standing a day or two, the small quantity of oil that distills over with the water, rises to the surface, is skimmed off. To produce one pound of oil, 2,500 pounds of roses are required, upon an average, though the yield is affected by the season, and is often much less. The annual yield of this district was 1,800 pounds, and about as much more was produced in all the rest of the country. The perfume is also produced in India, at localities on the Ganges, and elsewhere, is all consumed in the country.

Steam Plowing.—"J. G.," Polk Co., Minn. A steam plow is used by Landreth Bro., of Pennsylvania, the extensive seed growers. We know of no others in use this side of Louisiana. There are thousands in use in Europe and many in Egypt.

"Apple Saas."—In whatever the American agricultural and horticultural journals may be inferior to the English, it is not in courtesy to their readers. The English editor is often—to put it mildly—snappish. Our correspondents are often, no doubt, as unreasonable as theirs, yet we should think it on the north side of politeness were we to adopt the manner of the "Gardener's Magazine," and reply to a correspondent thus: "'E. S.' Not having time to name your thirty varieties of apples and pears, we have sent them to the kitchen, and have not seen them since,"—a plain case of "apple saas."

Will a Grain Drill Pay.—"C. M. C.," Bradford Co., Pa. A grain drill will cost about \$30. Its use will save half a bushel of seed per acre, and add a few bushels per acre to the crop; it will also sow grass seed and grain at the same time, and sow ten acres a day. One can easily see if it will pay to use a drill or not.

Long Island Lands.—Inquiries are made by various western publishers about lands on Long Island. It appears that nearly every paper in the north-west has received a proposition to give a named space in their advertising columns in exchange for a deed of an acre of land in Suffolk Co., L. I., and inquiries are made as to the character of the lands. Long Island is very long, and on it there is land and land; having a friend who was "born and raised" not far from the tract in question, we made inquiries, and learn that this very land was sold not long ago for 50 cents an acre. Our friend says it is the "sandiest kind of sand," and gives it as his opinion that whoever buys an acre of it at any price "will get stuck."

A Novelty in Furs.—An English fur-dealer thus winds up his advertisement: "N. B.—Capes, Victorias, etc., made up for ladies in fashionable style, out of their own skins." The Italics are ours.

Trouble with Hydraulic Rams.—"R. S. C.," Wakefield, Mass. As water absorbs a certain quantity of air, the air chamber of a ram in times be-

comes emptied of air and filled with water. This will always happen sooner or later, as the water contains more or less air, or flows from a rapid stream or a quiet spring. The remedy is to remove the air chamber and empty it of water and replace it, whenever the ram stops. By not understanding this, many persons unjustly find fault with this useful machine.

Air Beneath the Skin.—"Mrs. B.," Everett, Mass. The presence of air in the cellular tissue beneath the skin, causes soft fluctuating swellings. It is known as Emphysema, and occurs as a symptom in some acute diseases, and sometimes happens when no disease is apparent. It may disappear without treatment, leaving no ill effects, or be dislodged by puncturing the skin.

Farm Apprentices.—"J. J. M.," We know of no one who would be willing to take a young man as a student on a well-managed farm, and give him board for his services. The services of a novice upon a well-ordered farm are worth less than nothing, because he requires to be shown how to do everything, which is more trouble than doing it without such help. It is customary that a certain sum be paid as an equivalent for the trouble of teaching a novice in farming. Generally, \$300 a year is charged, which covers board.

Means for Cooking Feed for Pigs.—"H. H.," Shelburne, Vt. A common open kettle of large size, set in a brick arch, would serve very well to cook the food for 30 to 50 hogs. This would cost very much less than any of the other steaming apparatus made specially for this purpose.

The Black Board in the Sunday School.—by Frank Beard. New York, Jessc Haney & Co. As its title implies, this is especially intended for Sunday School instruction, but it is very useful for one who would learn the art of black-board illustration for any other purpose. A handsome work finely and abundantly illustrated.

How Superphosphate is Made Ineffective.—"H. B. S.," Franklin Co., Pa. Superphosphate is simply insoluble phosphate of lime that has been treated with sulphuric acid so as to separate a portion of the phosphoric acid from its base, the lime, and render it free and soluble. If the superphosphate is brought into contact with lime, as on newly limed land, the free phosphoric acid at once unites with the lime, goes back or "reverts" to the condition in which it was previously, and becomes insoluble and inert. Therefore, when superphosphate is used on land that contains fresh lime, it is practically useless, and is lost so far as present effects are concerned. Superphosphate should not be used until the second year after lime.

A Profitable Hen.—F. R. Kinney, Worcester, Mass., sends a portrait of his brown Leghorn hen, (Red Ribbon 2d), which has recently died. We suppose of old age, being ten years and two months old. During her life she laid 2,151 eggs, or an average of more than 210 each year of her life. This is not the only hen Mr. Kinney has had of this breed, that has been remarkably prolific of eggs; this goes to prove the frequently published statement, that a hen can only lay about 600 eggs in the course of her life, to be a mistaken one. Mr. Kinney claims this hen to have been the most prolific one ever reported.

Chemicals for Compost.—"D. S.," Bell's Valley, Va. It is not proper to mix soluble chemical fertilizers in compost heaps. They are more effective when used alone, and spread on the land at the season when they can do most good. For composts, those substances are needed which take some time to decompose, or those fermentable matters, which communicate their action to inert materials, and so cause them to rot more quickly. Lime or wood ashes may be used along with some yard manure, to set up a destructive fermentation in such matters as swamp muck, leaf-mold, or vegetable refuse; but the latter should be in the greater proportion than the former, else ammonia will be lost.

Value of a Fertilizer.—"W. P.," Cool Spring, Del. A fertilizer containing 24 per cent ammonia, and 10 1/2 per cent soluble and available phosphoric acid, is worth in the market about \$40 a ton. These are the usual constituents of what is known as "ammoniated dissolved bone," or superphosphate. In this shape the ammonia costs 30 cents a pound, and the phosphoric acid 12 cents. Generally all the ground bone of respectable manufacturers is pure; that from glue factories being deprived of its animal matter, is consequently devoid of ammonia; adulteration is only practised by obscure persons without reputation. If you buy from well known dealers or manufacturers, there is no risk of loss unless by accident, and then reparation will be cheerfully made.

Nuts and Nubbins.

There are floating around in the daily papers, numerous items which may afford our readers a pleasant variety if introduced occasionally among our matter of fact teachings. We have a strong belief in the utility of fun and laughter, and in complying with suggestions from several that we occasionally give some humorous items, we have collected a large number from the newspapers of the day. Upon looking these over to make a selection for our columns, we were surprised to find how few of the whole we cared to print. Aside from those lacking point, many were really irreverent and making fun of those things which all right thinking persons regard as sacred; others make light of marriage, and assume that the relation of husband and wife is of necessity one of mutual deception. A large share of fun is directed to the "mother-in-law." It may be that there are such mothers-in-law as comic writers regard as the type of this excellent class of women, but we are happy to say that we have met with none. If our selection of "Nuts and Nubbins" is small, it is because we think it better not to be funny at all, than to be so at the risk of injuring the feelings of any person or class. We take these items wherever we find them, without crediting their sources.

Greenland has no cats. Imagine cats in a country where the nights are six months long.

What is the difference between a hill and a pill? One is hard to get up, and the other is hard to get down."

A person who had been listening to a very dull address remarked that everything went off well—especially the audience.

Milly (just returned from a visit to her grandmother): "Mamma, what do you want a mamma for? You're too big to put in the closet."

A little girl, yesterday, while watching the rain, turned to her mother and said:—"Ma, I guess the weather's so warm it's melting the clouds."

The intention of the old deacon was good, but the way in which he worded his notice was infelicitous. He said: "Any members of this congregation who have left off wearing apparel will please contribute the same to the poor." A quiet smile pervaded the house, and the people thought that it would be hardly the proper thing to leave off wearing apparel in the chilly December.

English farmer (after anxiously inspecting strangers): "What be they gentlemen doing, maister?"—Visitor: "Sketching your house; they are artists, and may be they will paint it."—Farmer: "Well, I am sure they be welcome; it wants it, and whitewashing, too, mortal bad."

"Some little time ago I was instrumental in getting a cook for a newly-married friend. I did not often see my friend, and last week, upon meeting a sister of the cook, I asked her how her relative liked her place. "Oh, very well, sir! the master and mistress are quite gentlefolk; they don't know anything."

A Harvard student was called to account for having publicly styled the professor of Hebrew "a first-class mule." He admitted having made the remark, but said he intended it as a compliment. "Explain yourself," said the professor. "Why, a first-class mule is necessarily a good He-bray-ist." *Nol pro.*

One thousand shingles, says a newspaper paragraph, will cover one hundred square feet of surface. One shingle, by the way, will cover six square inches of bad boy, and, if properly applied, will be productive of as much benefit and more noise than one thousand shingles on one hundred square feet of surface. Figures won't lie.

A youngster who had been warned of the evil effects of mince pie heard a mouse squeal after he had been put in his crib and asked his mother: "What dat noise?" "Oh, it's a little mousey; it won't hurt," was the reply. After a few minutes' silence the youngster remarked: "Guess de mousey been cat miss pie 'fore he go bed, au' made he ky."

One of the pleasant events of Christmastide was the presentation, in one of the leading industrial establishments of Buglington, says the "Hawkeye," of a handsome gold watch and chain to each of the employees by the proprietor. Come to think it over, we believe it was the employees who presented a gold watch and chain to the proprietor. We thought we had never heard of a precedent for the former reading.

A man near Pittsburgh, Pa., recently advertised for a bookkeeper, and within twenty-four hours he had one hundred and thirteen applicants for the position. Subsequently he sought a man for his farm by the same means, and had eight responses. These figures represent very fairly the disproportion of laborers in the various industrial pursuits. There are men needed in abundance for agriculture and other manual labor, but when a young fellow is able to write a fair hand, and balance the day's transactions in a country store, he feels above the farm, the anvil, or the bench. This is all wrong, and is of a piece with the other inflated notions that prevail.

STOCKBRIDGE MANURES.

Originated by Prof. STOCKBRIDGE, Professor of Agriculture in the

MASS. AGRICULTURAL COLLEGE.

40 to 80 Bushels	Corn	per Acre,
25 to 50 "	Wheat	" "
20 to 40 "	Rye	" "
25 to 50 "	Barley	" "
150 to 250 "	Potatoes	" "
1500 to 2100 lbs.	Tobacco	" "
2000 to 4000 "	Hay	" "

and other crops in proportion, have been produced by the use of these manures alone. The results on Corn and Grass are truly wonderful.

A special manure is made for each Farm and Garden Crop, containing the Plant Food which each particular Plant requires. These manures were used on more than 10,000 acres in 1877, and with Great Success.

Send for Pamphlet for 1878, full of information, mailed free.

Soluble Pacific Guano.

The Superior excellence of this Guano has been so successfully demonstrated during the past ten years in the Middle and Southern States, on cotton, corn, tobacco, sugar-cane, and garden vegetables—the Company's sales having exceeded the enormous aggregate of 35,000 tons in a single season—that it is now offered for sale with entire confidence as to its merits. No fertilizer ever introduced in this country, has undergone severer tests, or come out of them with its character as a first-class, reliable fertilizer more thoroughly established. In consequence of the satisfactory results of these very complete tests, this Guano has acquired a reputation equal to that formerly enjoyed by Peruvian Guano. It is rich in **Bone Phosphate of Lime**, finely ground (a large proportion of which is immediately soluble), **Ammonia**, and **Potash**, besides other ingredients valuable as plant-food, manufactured at the Company's works, Woods Hole, Mass., and Charleston, S. C., under the supervision of competent chemists.

PACIFIC GUANO CO., BOSTON.

Matfield Fertilizer.

This is the only fertilizer professedly containing all the soil elements found in each crop. Prof. W. O. Atwater, of the Connecticut Agricultural Station, analyzed six of our different fertilizers, and found in every case, as we guaranteed, that they contained a larger percentage of plant-food elements than we claimed by the labels placed on each package. Send for circular. Address

F. COPELAND,

Treasurer and General Agent Matfield Fertilizer Co., 13 Doane St., Boston, Mass.

CHEAPEST FERTILIZER BECAUSE THE BEST.

PREMIUM BONE

Grows WHEAT and GRASS, equal to manure, at Half the Cost, and lasts twice as long.

Farmers!! Send questions on Postal Card to EXCELSIOR FERTILIZER WORKS, Salem, Ohio. Circulars Free.

THE UNION RAILWAY

HORSE POWER & Premium Thresher. This power produces much more power than other railway powers, with much less elevation. Send for Descriptive Circular.

VALUABLE ARCHITECTURAL BOOKS

Atwood's

Country and Suburban Houses.

This work is finely illustrated with about one hundred and fifty engravings, and gives instruction upon all points, from the selecting of a place to build, to the perfect completion of the house. By D. T. Atwood, Architect. Cloth, 12mo. Post-paid, \$1.50.

Hussey's

Home Building,

From New York to San Francisco.

It is EXTENSIVELY ILLUSTRATED, containing 42 Plates of Perspectives, with Plans of 45 Original Buildings, of as many classes, and their cost; and an INVALUABLE TABLE of materials, labor, and prices, at about 400 cities, towns, and hamlets, from the Atlantic to the Pacific. Also, complete and ELABORATE SPECIFICATIONS of materials and labor; merchandise, and where it may be procured. It also contains original descriptions and valuable statistics for 1876 of over 250 Cities and Towns. By E. C. Hussey, Architect, author of Hussey's National Cottage Architecture, &c. Post-paid, \$5.00.

Allen's

Rural Architecture.

Practical Directions and Suggestions for Construction of convenient Farm-Houses, Cottages, and Out-Buildings, including Barns, Stables, Sheds, Carriage and Wagon-Houses, Work-Shops, Wood-Houses, Ash and Smoke-Houses, Ice-Houses, Poultry and Bee-Houses, Dove-Cotes, etc., together with directions for the Gardens and Grounds; useful and ornamental Domestic Animals, etc. By Hon. Lewis F. Allen, Editor of "American Herd-Book," "New American Farm Book," etc., Cloth, 12mo. Post-paid, \$1.50.

Plummer's

Carpenter's & Builder's Guide:

Being a Hand-Book for Workmen, also a Manual of Reference for Contractors, Builders, etc. PART I. The first part treats of Building Materials, and contains a large amount of information concerning the quantity, quality, and cost of the materials required to build a house.—2. Problems for Drafting.—3. Description of Plates. Cuts for Boxes or Hop-

pers with flaring sides. Raking Mouldings. Roof Cuts, including Jack Rafters. Backing a Hip. To describe Hip or Gables for the intersection of Arched or Curved Ceilings. Stair Rails—First Example. Second Example.—4. Board, Plank, and Scantling Measure.—5. Form of Builder's Contract. From "Parson's Law of Business," by permission of the Publishers.—6. Glossary of Terms used in Architecture, and definitions of the same. Definitions of the most common terms in Drafting. By P. W. Plummer. Post-paid, \$1.00.

Lakey's

Village and Country Houses.

Or, Cheap Houses for All Classes, comprising eighty-four pages of designs. The object, in almost every instance of these designs, has been to secure as large an amount of space and comfort as was possible with the least expenditure of money, without neglecting the exterior features of each building. Royal Quarto. Post-paid, \$5.00.

Leuchars'

How to Build Hot-Houses,

Green-Houses, Graperies, etc., etc., and how to Ventilate them. Illustrated with numerous Engravings. This is the only work published in this country, specially devoted to this subject. By Robert B. Leuchars, Garden Architect. Cloth, 12mo. Post-paid, \$1.50.

Burn's

Illustrated Architectural, Engineering, and Mechanical Drawing Book,

A Self-Instructor for the use of Architects, Builders, Students, etc., with upwards of 300 illustrations. This is the best work published on Architectural Drawing, and will aid any persevering person to acquire a good knowledge of the subject. By Robert Scott Burn. Post-paid, \$1.00.

Burn's

Illustrated Drawing Book,

For Schools, Students, and Artizans. With 300 illustrative drawings and diagrams. Embracing the practice of pencil sketching. The practice of figure and object drawing. A full and complete explanation of the principles and practice of Perspective; also of Isometrical drawing. By Robert Scott Burn. Post-paid, \$1.00.

Burn's

Illustrated Book of

Ornamental Drawing and Architectural Design.

With upwards of 200 examples. Giving instructions in decorative drawing, illustrated historical notices of different styles of architecture, and a variety of architectural plans and details for practice. By Robert Scott Burn. Post-paid, \$1.00.

Either of the above books sent post-paid on receipt of price by

ORANGE JUDD COMPANY,

245 BROADWAY, NEW YORK.

HIGHEST AWARD at the CENTENNIAL.

Cheap, because so well made, durable, and efficient. Nine sizes made, churning from one, to 150 gallons. Warranted to be exactly as represented. Sold by all dealers in really first class Farm Machinery. PORTER BLANCHARD'S SONS, CONCORD, N. H., Sole Manufacturers. Send for Circulars.

SPAIN'S PATENT CHURNS. Centennial Medal Awarded. In use over 25 years. Removable Dasher. Made of White Cedar with galvanized hoops. Send for circular and prices. CLEMENT & DUNBAR, Philadelphia.

COOLEY SYSTEM FOR Butter and Cheese.

All the cream between milkings. No Skimming, no dust, no flies, no spoiled messes. Milk sweet for use after all the cream is off. Send stamp for circular. Vt. Farm Machine Co., Bellows Falls, Vt.

LILLY'S BUTTER-WORKER The cheapest and best Machine in the market; no hard labor required. Try it, and see for yourselves. Only \$15 for a thirty pound machine that will take all the milk out with five minutes' work.

HENDERSON & CO., 316 Race St., Phila., Pa.

BUTTER COLOR.

After fair trial and severe tests it was awarded Centennial Prize Medal. WHY IT IS SUPERIOR TO ALL. 1st. It has no taste or smell, and is as harmless as water. 2d. It is liquid, is easy to handle, and is mixed in cream before churning. 3rd. It produces a color resembling June Grass Butter. 4th. It is the only article that will color the butter and not the buttermilk. 5th. It gathers all butter materials, increases the weight more than will pay for the color used. It is the best ever known. Send your address on postal card for my receipt book, free. It tells how to make butter, pack, preserve, extract ranchfully. MRS. B. SMITH, 327 Arch St., P. O. Box 1854, Phila., Pa.

BUTTER WORKER.

The most Effective, Simple and Convenient Yet Invented. Works 30 lbs. in less than 5 minutes, thoroughly working out the buttermilk and mixing in the salt. Send for circular and price lists.

A. H. REID, No. 6 North 18th St., Philadelphia Pa.

GOOD MEN WANTED

to sell the celebrated cow fitter. It sells on sight. Warranted to make the worst kicking cow gentle to milk, in three days. There is nothing equal to it for breaking her. Retail price \$2. For further information send for illustrated circular to

HARDWARE and CUTLERY.

Builders Hardware.—Everything necessary for building or repairing the House, Barn, or Outhouses. **Machinists Hardware.**—Screws, Washers, Bolts, Wrenches, etc. **House Furnishing Goods,** including Refrigerators, also Farming Implements and Tools of all kinds

JOSEPH T. FARRINGTON, 32 Howard St., New York City.

Equally adapted to Ladies' and Children's thin Shoes, as well as to the thick and heavy boots of the Lumberman. Packed in Boxes containing 1 Doz. 4-oz. bottles, with Directions for use. Address

TUNYOAP MANUFACTURING CO., 46 India St., Boston, Mass.

THE WALKER WASHER.

Thousands of Them in Actual Use. They are a Perfect Success. Simple, Durable, and Cheap.

Agents wanted in every town where they are not already being sold. Retail price \$8. Send for circular. Address ERIE WASHER CO., Erie, Pa.

BEES AND HONEY.—If you wish to learn all about bees and how to manage them successfully, send 50 cents for our 64-page pamphlet containing a beautiful life-like chromo of Italian Bees in their natural colors, the Prize Essay on bees by Mrs. Tupper, Queen Bees by Quinby, instruction for beginners, etc., etc., with the Bee-Keepers' Magazine 4 months

beginning September, 1877. The November number contains the full report of the National Bee-Keepers' Association at the three days convention, in New York City. The Southern Department of our Magazine is conducted by Dr. Brown, of Augusta, Ga. Annual subscription, \$1.50. Bee-Keepers' Text-book, 40 cents. For the best Bee-Hives, Honey or Wax Extractors, Bee Books and all other bee-keeping supplies, address A. J. KING & CO., 61 Hudson Street, New York.

FRIENDS! If you are in any way interested in BEES OR HONEY,

We will with pleasure send you a sample copy of our MONTHLY GLEANINGS IN BEE CULTURE, with a descriptive price-list of the latest improvements in Hives, Honey Extractors, Artificial Combs, Section Honey Boxes, all books and journals, and everything pertaining to Bee Culture. Nothing Patented. Simply send your address on a postal card, written plainly, to A. I. ROOT, Medina, Ohio.

CORBETT'S INCUBATOR and Mother combined, 100 eggs capacity, \$25. 17 Gold, Silver, and Bronze Medals received. Testimonials and Catalogue sent on application. Prof. A. CORBETT, 7 Warren Street, New York.

HOW TO LIVE IN FLORIDA, HOW TO GO, COST OF TRIP, COST TO SETTLE, what to cultivate, how to cultivate it, etc., etc., all told in each number of Florida New-Yorker, published at 21 Park Row, New York City. Single copy, 10c., one year \$1. 40 Acres Orange Land for \$50. On line of railroad, country healthy, thickly settled. Address J. B. OLIVER, Gen'l Agent, Box 5520, New York.

MONEY Made rapidly with Stencil and Key Check Outfits. Catalogues and Samples FREE. S. M. SPENCER, 112 Washington St., Boston, Mass.

TUTTLE KNITTER For Family Use In the Market. For Circular, Sample, and Full Particulars, Address

LAMB KNITTING MACHINE Co., Chicopee Falls, Mass.

Take it Easy. Common-Sense Chairs and Rockers.

With or without Reading Table. For sale by the trade. Manufactured by F. A. SINCLAIR, Mottville, N. Y. Send stamp for Illustrated Price-list. Be careful that the chairs are stamped with my name in full; others are IMITATIONS.

FELT CARPETINGS 20 to 45 cts. per yard. **FELT CEILING** for rooms in place of Plaster. **FELT ROOFING and SIDING.** For circular and Sample, address C. J. FAY, Camden, N. Jersey.

The Racine Iron Works

MANUFACTURE Florists' & Ornamental Iron Goods,

Ferneries, or Warden Cases, Aquaria, Fountains, Vases, Brackets, Plant Window Boxes, Flower Stands, Chandeliers, etc.

S. FREEMAN, Proprietor, Racine, Wis. Send for our Illustrated Catalogues.

BRICK AND TILE MACHINE.

TWENTY YEARS standing as a TILE MACHINE, and without a rival as a BRICK MACHINE. For circulars address J. W. PENFIELD, Willoughby, Ohio.

Splendid Chance For a Home in NEBRASKA.

Some VERY DESIRABLE FARM LANDS, located close by the Railroad, in the rapidly growing State of Nebraska. They can be had at a Bargain in amounts to suit purchasers. Address immediately, AUGUSTIN SNOW, No. 2 Exchange Court, Room 4, New York City.

INTERNATIONAL EXHIBITION For Agricultural Machines & Implements, HAMBURG, 1878.

From the 13th to the 17th of June, 1878, under cooperation of the Section for Agriculture and Horticulture, at Hamburg, and the Union of German Manufacturers and Dealers in Agricultural Machinery, an International Exhibition of all kinds of Agricultural and Garden Implements, will be held in Hamburg, Germany. It is well known that the endeavor of the above named Union has been to liberate manufacturers from the necessity of sending their goods to all Agricultural Exhibitions, whether large or small, enabling them thus to sell their manufactures at lower rates to the farmers. This result is intended to be obtained by limiting the number of exhibitions to the commercial centers of the German Empire, to be periodically repeated. For Northern Germany, Hamburg appears to be the most favorable place, where the various railroads, etc., connect with the seaport, and this leads to the hope that foreign nations will be represented there, so that the farmers and peasantry who will visit the exhibition may have the opportunity of witnessing a complete collection of all kinds of tools for husbandry, and systems in all parts of the world.

Plans and directions for sending to these International Machinery Markets, will be sent, free of charge, from the office of the undersigned committee, 25 A B C strasse, Hamburg. The committee for the International Agricultural Machinery Exhibition at Hamburg, in 1878: ALB. VON OHLENDORFF, President; HERM. SCHEMMANN, Treasurer; Dr. RICHARD SEELEMANN, Recorder; CLAUD OLDE, S. MAGNUS, Engineer. HEHRMANN H. BIEBER-TATENBERG, G. F. SCHWABE-WALTERSHOF, COUNT VON HOLSTEIN-WATERNEVERSTORFF, W. H. BOCKELMANN, K. J. JOHANSEN-SCHIELE, B. HENNEBERG-PÖPPENBURGER, Counselor, KUSTER-SILLIUM, Chief Steward, CREYDT-HARTE, G. J. BOCK-GR. WELTZIN, GRAF ZUR LIPPE-WEISSEN-FELD, in Klostok. General Secretary PETERSEN, Oldenburg. Engineer KAYSER, Berlin.

THE HARVEST OF 1878.

For description of **A Wonderful Improvement in Harvesting Machinery**, see page 400, October number *American Agriculturist*. For further information address Whiteley, Fassler & Kelly; Champion Machine Co., and Warder, Mitchell & Co., of Springfield, O., and The Toronto Reaper and Mower Co., Toronto, Canada.

PRESS CO.,
SYRACUSE, N. Y.**

YALE VERTICAL MILLS, and Yale Vertical Engines.

The best built and best finished Machine in the Market. "The best is the cheapest."
The Yale Vertical Mill has an iron frame, and the very best of French Burr Stones, is self-oiling and self-feeding, and for quantity and quality ground it has no superior. Adjustable-balanced; long bearings, best arrangements, and in every respect it is the cheapest mill ever offered.
The Yale Vertical Engine is the best and most economical for either land or marine use, and is especially adapted to all farm purposes. We also manufacture Horizontal Engines, either with or without the Rider cut-off. Rubber and Punching Presses. Send for illustrated circular. **YALE IRON WORKS, New Haven, Conn.**

Farmers Friend Grain

And Fertilizer Drill.

The quantity is regulated with gear-wheels in a CONE, so there are no loose wheels or movable feeders, and it will sow any grain perfectly and accurately.

It has the best Spring Hoe, and every Drill has a Force-Feed Grass-Seeder, Patent Shifter, and Surveyor free.

Illustrated Catalogues, with description, prices, and a Full Centennial Report, sent on application. Agents wanted in unoccupied territory. Address, stating where you saw this notice,

**FARMERS' FRIEND MANUF'G CO.,
Dayton, Ohio.**

The Birdsell Clover Separator,

SOUTH BEND, IND.

The Chamberlin Screw Stump Machine, after 10 years test, has proved its superiority over all others, by its great exhibition of strength and durability, combined with cheapness and ease in pulling all classes of stumps. The Company's challenge of \$100 for a stump machine which would excel theirs, has stood since 1867 without being taken. They build 6 different sizes of machines, to pull all kinds of stumps. They make Subsoilers and Ditching Plows. For Particulars, Prices, etc., address **THE CHAMBERLIN MFG CO.,** Olean, N. Y.

IXL Feed Mill.

This mill is the cheapest, most durable and perfect iron feed mill ever offered. It is simple, easily managed, and can be run by Wind, Steam, Water, or Horse power. The chilled iron plates have grinding surfaces on both sides and can be reversed, thus making one set equal to two on the old plan. An extra set is sent with every machine, and the two sets will grind Four Thousand Bushels of good feed. New plates can be had for \$1.25 per set. These mills are built wholly of iron, (except the Hopper,) are strong, efficient, and durable. Thousands are in use on Stock Farms—every one giving excellent satisfaction. Every farmer should have one and grind his own feed. Send for Catalogue and Price List to

**U. S. WIND ENGINE & PUMP CO.,
Batavia, Kane Co., Ill.**
Manufacturers of Halladay Standard Wind Mills.

250 MARYLAND FARMS, in Tracts from 30 to 300 acres.

BACK VOLUMES OF
American Agriculturist.

The publishers of the *American Agriculturist* can supply any of the back volumes of that paper from the Sixteenth to the Thirty-sixth. These volumes contain more varied and interesting information on all matters pertaining to the Farm, Garden, and Household, than can be obtained in books costing three times as much money. Price of each bound volume, at the Office, \$2.00; sent post-paid, \$2.30.

A Book for the Fireside in the long Winter Evenings.

The Farm-Yard Club of Jotham.

An Account of the Families and Farms of that Famous Town.

By GEORGE B. LORING.

NOTICES BY THE PRESS.

The Farm-Yard Club of Jotham, an Account of the Families and Farms of that Famous Town, so happily combines the information which both the amateur and the professional farmer need, with the charms of individual experience and characterization, that it will please a great variety of tastes. The number and excellence of the illustrations deserve special mention, the designs being tastefully conceived and skillfully executed, and having, moreover, a peculiar appropriateness.—*Globe*, Boston, Mass.

Dr. Loring has given us a book which is at once encyclopaedia in its information, entertaining for its wit and humor, and interesting as a story, for the bright thread of real life and love that runs through it.—*Golden Rule*.

Octavo, 608 pages, with 70 illustrations of Characters, Country Scenes, Farm Animals, and Implements, by Champney, Rose, Lathrop, Forbes, and others. Price, post-paid, \$3.50.

HOW TO USE THE MICROSCOPE.

NEW EDITION—NOW READY.
PRACTICAL HINTS
ON THE SELECTION AND USE OF THE
MICROSCOPE.

INTENDED FOR BEGINNERS.

By JOHN PHIN,

Editor of "The American Journal of Microscopy."

The great favor with which this book has been received, has encouraged the publishers to prepare an entirely new set of plates for it. The new edition, therefore, is not a mere reprint of the old, but will be enlarged to nearly double the size, and at the same time will be improved by the addition of some thirty or forty illustrations, including four full page engravings, handsomely printed on fine toned paper. Notwithstanding these additions and improvements, the price will remain the same—75 cents, post-paid.

Either of the above books sent post-paid on receipt of price by

ORANGE JUDD CO., 245 Broadway, New York.

A Trochar for Cattle-Men.

In June of 1872 we gave illustrations of a Trochar and Canula to be used in ringing a bull, and on page 13 (January) and page 97 (March) of the *American Agriculturist* for 1873 (copies of which may be got from this office for 15 cents each) we described the use of this apparatus in relieving hoven in cattle. These articles have brought out a large demand for Trochars, and failing to find just the right kind among the makers of surgical implements, we have induced an establishment to undertake their manufacture. We give herewith a small engraving of the Trochar. These articles are now in the trade, and may be had of most dealers in agricultural implements. Those who can not get them from dealers can receive them from this office, prepaid, for \$1.00.

ORANGE JUDD COMPANY, 245 Broadway, N. Y.

A COPPER BULL-RING.

2½ inches in diameter, of the most approved pattern, with screw-driver for putting it together, will be sent, prepaid, on receipt of \$1.00. Address

ORANGE JUDD COMPANY, 245 Broadway, N. Y.

THE CHROMOS.

To every Yearly Subscriber to the *American Agriculturist*, the Publishers will present an exquisite Chromo, as detailed below. Two beautiful Oil Paintings, executed expressly for the ORANGE JUDD COMPANY, and entitled "MISCHIEF BREWING," and "UP FOR REPAIRS," were reproduced in chromo in the finest style. As long as any of these are in stock, a choice will be given to yearly subscribers of either one of them, without reference to other offers made elsewhere to our subscribers.

The chromo selected will be delivered at 245 Broadway free of charge. If to go by mail, 10 cents extra must be sent to cover cost of packing and postage. For 25 cents it will be Mounted, Varnished, Packed, and sent Post-paid.

JOSEPH T. FARRINGTON,
32 Howard St., New York City.

THE "Model Piano."

PRICE \$150 to \$200.

The "MODEL" is a beautiful little Upright or Cottage piano; it is manufactured from the best materials that can be procured; the workmanship is excellent, and its durability is guaranteed; it is small, light, and occupies but little room, is easily transported, and above all the "MODEL" is sold at about one-third the price that is usually paid for any other reliable piano. For the above reasons, it is very suitable for people of moderate means, and those living in small houses; but it is especially adapted for beginners, and on account of its low price, commends itself to every parent, because it possesses all the principal features of the finest houses; and has none of the numerous disadvantages of the cheap piano.

For full particulars write for illustrated pamphlet, and state where you saw this notice.

SIMPSON & COMPANY,

PATENTEES AND MANUFACTURERS,

No. 5 East 14th St., N. Y. City.

MAPES' GRASS & GRAIN SPRING TOP-DRESSING.

For top-dressing in the spring "WINTER-KILLED" grain, or for use in the hill or row upon any crop where very quick growth is desired.

Wheat crops, which had been nearly destroyed by "winter-killing," were recovered last spring and made profitable by a dressing of one and two bags per acre of this manure.

The land is left in improved condition for a succeeding crop.

Adapted also for GRASS PLATS and LAWNS. Apply in early spring. Directions for use accompanying each bag. No disagreeable odor.

Price per ton.....\$51.00

per single bag (200 lbs.)..... 5.35

Cartage for less than half ton, 50 cts.

Our new descriptive price-list contains analyses of the leading fertilizing materials, formulas, etc., including all the fertilizers selected by Prof. W. O. Atwater, Middletown, Conn., for his system of experiments by farmers. The Price List and Circular in Leading Crops furnished gratis. Address

THE MAPES FORMULA and PERUVIAN GUANO CO.,
158 Front Street, New York.

USE THE PERFECT BUTTER COLOR!

WELLS, RICHARDSON & CO'S PERFECT BUTTER COLOR is recommended by the agricultural press, and used by the very best dairymen in this country. Harris Lewis, L. B. Arnold, O. S. Bliss, L. S. Hardin, A. W. Cheever, E. D. Mason, and thousands more. It is far better than carrots, annatto, or any other color, at one-fourth the cost, and no work to use. It gives a pure dandelion color, and never turns red, or rancid, but tends to improve and preserve the butter. A 25 cent bottle colors 300 pounds. Warranted to add 5 cents per pound to its selling value. Ask your Druggist or Merchant for it, or if you would like to know what it is, what it costs, who uses it, and where you can get it, write to

LIGHT BRAHMAS AND JAPANESE BANTAMS. — Drawn and Engraved for the American Agriculturist.

Portraits are given above of fowls of two conspicuous breeds. One is remarkable for its large size, and the other for its diminutive, as well as picturesque and odd appearance. The Light Brahma is now well known amongst breeders and fanciers, but is not yet nearly so popular amongst farmers, and those who rear poultry for market, as it should be. The above portraits are drawn from life from some birds bred and owned by Messrs. Magrane & Fairservice, of Woodside, near Newark, N. J. These gentlemen, who are well known amongst fancy poultry breeders, have been more than usually successful in taking premiums at exhibitions, and their birds are in great demand, not only at home, but in foreign countries. Some fine specimens were recently sold and shipped to an English breeder. After an inspection of their poultry, the selection of a pair for illustration was no easy matter, as it was difficult to choose where many were worthy of the distinction. Having so frequently described the Light Brahmas, we need not now repeat their characteristics, but merely

point out here, the small head, the lofty carriage, the broad full breast, the deep round body, the short stout limbs, all of which mark the high-bred bird, and one producing a great amount of flesh with the least offal. This is one distinguishing feature of the Brahma fowl, which renders it a profitable breed for the farmer. No other bird excels it as a winter layer, and as it is a good mother, the plentiful fluff about it serving to keep the chicks warm in the coldest weather, and as the chicks are hardy, it is easy to have very early birds. The young birds, as broilers, are remarkably juicy, well flavored, and tender, and the young cockerels of 4 to 6 months, weighing, as they easily do, 8 to 9 lbs., make most excellent roasters. As with all high-bred, pure races, the half-bred crosses of these, on the common stock, are nearly as good as the pure bred. There is no breed that excels the Light Brahma as the farmer's fowl. To introduce one young cock for every 25 common hens, would be to easily double the value of the farmer's yearly product. This we can say after several years' ex-

perience, during which our main stock has been of this breed, and having had occasionally some hundreds of cross-bred chickens for the market.

The Japanese Bantams, from which the portraits were taken, are also the property of Messrs. Magrane & Fairservice, who, to save trouble, request us to state that they have none of these birds for sale this season. These quaint little creatures are drawn in proportion to the larger birds, and weigh a pound and a quarter each. The plumage is white, excepting some of the wing feathers, the tail, and sometimes the tips of the neck feathers, which are black. The legs are bright yellow. The tail is the most curious part of this breed, being large, and carried so erect as to nearly touch the head. The legs are so short as to be almost invisible, and this gives the birds a curious creeping sort of gait. The little hens are exemplary mothers, and one of them, with a brood of tiny chicks, would be the delight of a boy or girl, as well as attractive pets for old folks. This breed has the virtue, rare amongst bantams, of being exceedingly peaceable and quiet,

Western Dairying.—It is but a short time since the term "Western," as applied to dairy products, was held to denote an inferior quality and a low price. Enterprising Western dairymen chafed under the reproach and the injury which, to some extent, resulted from this condition of things. They went resolutely to work to change it, and have succeeded. Now the best Western creamery butter is sought by the fine grocery dealers in New York and other cities as the best they can offer to their exacting customers, and it is sold at wholesale at 5 cents per pound above the prices of the best Eastern butter. "Western," therefore, is no longer a term of reproach, so far as the butter of the best makers is concerned. But there is still large room for improvement, for common "Western" butter is yet sold for grease, and brings 8 to 10 cents a pound, when the best brings 35 to 40 cents, and poor Eastern butter brings 16 to 20. The above remarks apply to cheese. Western cheese has of late taken the first premiums at exhibitions in competition with that from Eastern dairies.

AMERICAN AGRICULTURIST.

NEW YORK, MARCH, 1878.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every paper, from the latest experience and observations, by practical men in each department.]

While the past winter has been, as regards weather, one of the most pleasant, in some other respects it has been uncomfortable, not to say disastrous. Probably never before "in the memory of the oldest inhabitant," have the country roads been in such wretched condition. The impassable state of the roads in the Western, and in some of the Middle and Eastern States, has almost totally stopped traffic, and has seriously affected general business. Fortunately, many farmers had sold and delivered much of their wheat, and had thus secured a fair price in good time; but the corn crop has been left in the fields, either unhusked, or in piles, exposed to the weather. We hear much complaint of heavy losses of corn in this way, and a great loss on account of the bad condition of the bulk of what was secured. There is in this a costly and pertinent lesson to farmers. We must "mend our ways" in this respect. Without roads, civilized man is reduced to the helpless condition of the savage. Hundreds of millions of dollars have been spent in building railroads, and the bulk of the expenditure has directly, or indirectly, come out of the pockets of the farmers; but all this costly provision for carrying freight to market is totally useless, without passable country roads, by which the railroads can be fed. We have lost sight of this absolute necessity for good country roads. We have ignored the fact that bad roads are one of the heaviest taxes to which agriculture is subjected. We have submitted year after year to the annoyances and losses occasioned by our miserable roads, and still it is probable that unless attention is persistently drawn to this subject, it will be overlooked so soon as the occasion has passed away. During winter, we can neither make nor repair roads; and when "settled weather" comes, we can get along pretty well without repairing them. In this way we worry along. Our whole road system needs changing. This has been frequently set forth in this Journal, and will be again as opportunity offers. But certainly one of the most important and obligatory duties of the farmer, is the construction and proper maintenance of roads that can be used at all seasons of the year.

Hints for Work.

With the Return of Spring come floods and freshets, and much damage will result unless prevented. Wash-outs of roads, fields, yards, etc., may be averted by providing a number of outlets for the water at the places where it first gathers. Here it should be spread in several channels and prevented from gathering into a dangerous stream.

Water Furrows should be carried as little below a level as possible, and there should be so many of them that none will overflow into the others. By diverting the wash of roads from the gutters into small channels, the water charged with fertilizing matter may be spread upon the fields, and damage to the roads prevented.

Drains should be cleared of waste matters, such as leaves, and other trash that will interfere with the flow of water. In digging open drains, the earth should be thrown out upon the side opposite to that from which the surface water comes. In all the provisions made for carrying off surface water, the following principal points should be looked to, viz.: give the water the easiest possible channel; keep it in many small streams; avoid anything that will prevent easy escape for the water from the channels; provide an outflow into a stream or pond, or take care that it escapes where it will do no damage.

Planting Corn may be begun in the South this month. It is frequently planted late, with a view to save one working. The early planted corn gives the best ears, because these are well forward before the hot, dry weather of July can stop the growth; and the cultivating of a forward corn crop does not interfere with working the cotton. It is more convenient to have these two kinds of labors follow each other than to allow them to occur at the same time.

Shallow Planting is preferable for an early crop, when the soil has not been thoroughly warmed up.

Fodder Crops, such as corn planted in drills, and millet, will be found very valuable, and one can hardly have too much of them. These all go into manure for the farm; and the more fodder to feed, the more grain will be made, and the more cotton there will be to sell. By planting these crops early, damage by dry weather will generally be avoided, or a second crop may often be taken after the first is harvested. Green fodder crops exhaust the soil very little, but heavy crops require rich soil.

Top Dressing Grain Crops.—It is now that we require rapid, vigorous growth, to send up strong spears from the tillering roots. A moderate dressing of some active fertilizer, rich in ammonia, and with a good supply of phosphoric acid for the needs of the grain, is precisely what is needed. We do not point out here what fertilizer should be used. Several kinds, suitable for this purpose, are mentioned elsewhere. Where the wheat or rye was top-dressed in the fall, 100 pounds per acre may be sufficient now; otherwise 150 pounds would be needed.

Selection of Seed.—The corn crop may be greatly increased by selecting the best seed. There are varieties now coming into use which have the habit of bearing more than one ear to the stalk. If we can grow corn that produces only two ears to each stalk, it will be easy enough to produce 100 bushels per acre. But it is unsafe to experiment largely. Plant the main crop with what is known to be safe, and try new kinds in a small way at first.

Improved Seed, like improved stock, must be grown with special care, or it will rapidly go back to its original state. In experimenting with new kinds, every care should be given to keep up the vigor of the plant and maintain the character of the product.

Artificial Fertilizers.—The use of some active fertilizer early in the spring will be beneficial on almost all crops. When used with discretion, these are very profitable. But at this season only those that are perfectly soluble will be found available.

Early Potatoes.—Where the season permits of early planting, and this crop is already in the ground, it will be necessary to keep the sprouts slightly covered with earth as a safeguard against frost. By planting early, and hastening growth by frequent cultivation, the first crop may be gathered in time for a second planting. Where there is easy communication from southern fields to northern mar-

kets, few crops pay better than early potatoes, and in the Northern States, early planted potatoes may be harvested and sold in time to take a crop of corn fodder, corn, or millet, from the same land.

Flowing.—In the northern part of the country we are only as yet thinking about plowing and sowing. Here we find it best to be careful about putting the plows to work too soon. The soil should be dry enough to crumble before it is turned. Where a fallow is to be plowed for corn, it may be done as soon as may be; but sod ground should be left as long as possible, so as to get a good growth of clover to turn under. Steel and equally hard, chilled-iron plows have become so cheap and common, that every farmer may procure one. They are of easy draft, and scour perfectly in any soil.

Spring Cultivation.—In time, no farmer will fail to cultivate the fall-sown crops, just as corn or roots are now cultivated. We greatly need a machine for hoeing wheat and rye, by which the product will be much increased. At present only comparatively few farmers harrow these crops in the spring, while every one could, and should, do so. The ground should be dry on the surface before this is done, although the frost may not be out of the sub-soil. The object is to break up the crust and mellow the ground; this is done perfectly by either of the sloping-tooth harrows illustrated in Jan., pp. 18, 19.

Spring Wheat.—A new variety of spring wheat, which would be as good in its way as the Clawson, and some other new fall wheats, would be an acquisition. Two new varieties are offered by B. K. Bliss & Sons which, as far as can be judged by the appearance of the grain, seem to be well worthy of a trial. This crop needs early sowing, and a liberal dressing of Nitrate of Soda will help it amazingly.

Oats are hardy, and may be sown as soon as the frost is well out of the soil, if the seed is well covered. It will be found preferable to drill in the seed, rather than to sow broadcast. We always sow clover with oats, if it is convenient, and have never found the crop to shade the ground too much.

Clover Seed is cheap, and although it may not be sown until next month, a sufficient supply should be secured at once. No one knows how soon an advance in price may occur. Where there is no danger that the ground may wash by heavy rains or melting snow, clover seed may be sown towards the end of the month upon the snow. It will not sprout until the ground becomes warm.—The best time is on a still morning, after a little night freezing, which opens cracks all over the surface. The seed drops into these, and is covered as the ground thaws.

Meadows and Pastures are frequently injured by pasturing as soon as the snow is off. Nothing is gained, but damage results from such a course. As soon as dry enough, roll the surface thoroughly. Sod heaved by frost is restored by rolling, and stones or lumps are pressed down smoothly. The good effect will be appreciated when the mower is used. Walk behind the roller and pick up and throw into the box stones that may project enough to catch the mower blade.

Live Stock.—Although spring begins this month, for stock it is practically winter for some weeks yet. As warmth increases, some exercise in a dry yard is useful. When the melting snow or rain floods the barn-yard, the animals should be removed. It would be advisable to keep the yards dry if possible, by drains leading to a field where the liquid manure will be serviceable. By some means the feet of animals should be kept out of half frozen slop or mud in wet yards.

Feeding Young Stock.—It is often but wrongly considered that anything is good enough for young stock. On the contrary, nothing can be too good for growing animals. Coarse, indigestible, and especially musty food, is very injurious to them. It disorders the digestion, and produces diarrhoea, red-water, and impacted rumen; or paves the way for an attack of "black-leg," or other anthrax diseases, when the change to green food comes. Plants affected by smut, rust, and other fungoid diseases are, when used as food, most dangerous in their effects, and should be most carefully avoided.

Horses.—The breaking up of winter brings heavy

roads and severe work for teams. When extra exertion is called for, it should be done deliberately and with caution. Chains and harness should be strong; sudden jerks are dangerous to the teams, harness, and wagons. Above all things a driver should be patient and gentle. Willing animals should never be fretted by the obstinacy or stupidity of ignorant hired men. Just now let the farmer keep a sharp eye on his horses.

Cows.—For the management of cows at this season, see hints for the past two months.

Sheep and Lambs.—Upon warm days the ticks will be active, and the sheep may be noticed rubbing themselves against walls and fences. For ticks, a pint of a solution of Buchan's "Carbolic Dip" may be poured on to the sheep through the spout of a common kerosene oil can. Part the wool along the back, and pour the dip so that it runs down the sides.

Swine.—Sows that have not been bred, may be coupled this month. This will bring the pigs in June, and give time to have market pigs for the holidays, or fine store pigs for wintering over.

Vermis.—As the sun gets warm in the middle of the day, lice will become troublesome upon calves, pigs, and fowls. Nothing is so fatal to lice as grease. A mixture of lard and kerosene oil is very disagreeable to these pests. Put the mixture wherever it will do the most harm to the parasites and the most good to the infested animals.

Poultry.—It is now that the early layers will become broody. March or April chicks are very profitable, and every broody hen should be set at once. Give clean nests of oat-straw or hay, and put a handful of feathers under the eggs to keep them warm when the hen is off of the nest to feed.

Catarrh and Roup.—We have never seen so much disease amongst poultry as in the present season. There are many half blind hens whose sight might have been preserved by a little care. When the eyes become gummed up and the nostrils discharge, it is first catarrh, and then follows roup. Wash the heads and eyes with warm water and vinegar, and then touch the nostrils and the throat with a feather dipped in a solution of a pinch of chlorate of potash in a tablespoonful of warm water.

Notes on Orchard and Garden Work.

There is no month of all the twelve, for which it is more difficult to write these Notes, than March. It is on the border between winter and spring, and while in the northernmost localities winter still lingers, our readers in the Middle and Southern States are fairly in the midst of their spring work. As in other months our Notes are a little in advance of the season, as it is very easy for the reader to look back, should he find what we have indicated for March is with him practicable only for April. Those who have neglected to order trees, plants, seeds, etc., until now, should lose no time in procuring their supplies.... "Where shall I buy?" is a question frequently asked by correspondents, especially by those who have had no experience in purchasing. As we do not, knowingly, admit the advertisement of any one, from whom we would not purchase ourselves, we decline recommending one dealer in preference to another. The mail facilities allow seeds and small plants to be sent to remote localities. With regard to more bulky articles the matter of transportation is to be considered, and one will naturally purchase near home, if he can be well served, but if there is any doubt as to this, no consideration of saving of freight should prevent ordering from a nurseryman of good reputation.... In the hurry of spring work do not be tempted to plant, plow, or work the soil in any manner, until it is sufficiently dry, and will crumble as it is moved by the spade or plow.

Orchard and Nursery.

Injured Trees should be looked to at once. If limbs have been broken by accumulations of snow and ice, make a smooth wound and cover it with melted grafting wax or thick paint. Trees that are

Girdled by Mice or Rabbits, if the inner bark is not destroyed, will recover if well earthed up, or by the application of a thick plaster of cow dung and loam,

bound on by a coarse cloth, the object being to keep the parts from drying until the wound can be healed. Where the girdling is complete, and the inner bark quite removed, the only chance of saving the tree is to insert

grafts between the bark above and that below. Pieces of the shoots of the same tree are sharpened at each end, and cuts made in the bark by a chisel, pointing downwards below the wound, and pointing upwards above it; the cions, as we may call them, are then inserted

as in the engraving, and the wound covered with clay or grafting wax.

Planting need not be hurried. When trees arrive from the nursery, unpack them, keeping a sharp eye to the labels, and "heel-in" at once. This is done by opening a trench and placing in the trees in a sloping position with their roots well covered with fine soil. This should be done if only a day is to intervene between their arrival and their planting, and when thus cared for, they remain for days or weeks without harm.

Pruning before Planting is of great importance. No matter how carefully a tree may be taken up, a large share of its fibrous roots are lost, and the top should be cut back in proportion. The tree as received from the nursery will probably have four or five branches, and if planted as it is, only a few of the uppermost buds on each branch will start. It should be cut back to leave but three or four buds on each branch. Novices hesitate to do this, but it is all important to the future welfare of the tree. At the same time all bruised roots should be cut back to sound wood.

Laying out the Ground may be done in squares, the trees in rows, and opposite each other, a common plan for small orchards, but where the ground is to be used to the best advantage, the *quincunx* method is adopted, in which each tree stands at the corner of an equilateral triangle, and is equally distant from six others. For any plan, the ground should be measured and staked out beforehand.

In Planting, recollect that the tree is not a post, but a broad and shallow hole is needed, in which the roots can be spread to their greatest extent. If the soil is poor, some good compost may be added, but no fresh manure. Set the tree so that it will be just as it stood before removal. Spread the roots equally, and work the soil in among them, and especially under them with the fingers, and cover gradually. When the roots are well covered, the soil may be pressed down gently with the foot, not stamped down, and the filling finished.

Stakes, where trees are properly planted, are not needed, unless in exposed localities where there are strong winds, and in such cases the orchard should be protected by a screen of some quick-growing trees that will serve as a wind-break.

Mulching newly planted trees is often highly important, whatever will prevent evaporation from the soil will answer. In some localities stones are the most available mulch. Use bog-hay, pine-needles, straw, or whatever will cover the surface.

Recording the Orchard should not be omitted. Labels soon become obliterated, and are unreliable, but a map, or a record by rows, is permanent.

Grafting is best done just as vegetation starts. A tree that produces poor fruit is easily converted into a profitable tree. The operation is a simple one, and any intelligent boy can perform it. It is not practicable for us to repeat these instructions every year. A very full and detailed account was given in April, 1877, which may be procured for 15 cents.

Old Trees may be renovated by cutting out the crowded branches, manuring, and giving the trunk and larger branches a wash of ley or soft soap, and scraping, as recommended last month on page 51.

Crops in the Orchard.—A young orchard may be cultivated with manured crops, such as potatoes and root crops, but when the trees come into bearing, they need all the soil to themselves.

Insects.—See for these, and other timely matters, last month's Notes.

Fruit Garden.

Whatever preliminary work remains should be disposed of, such as delayed pruning of grapes, currants, etc.; the making and repair of trellises and supports for grapes, raspberries, etc., and other matters hinted at last month.

Planting should be done as early as the soil is in good working order, that the plants may get well established before hot weather. Manure is to be given liberally, and nothing is better than well decomposed stable manure. The whole soil of the garden should be well enriched, if fine fruit is expected. Ashes are useful here, and a dressing of lime once in 4 or 5 years will often be of great help. In mentioning varieties, we name a few of the most reliable, referring to the catalogues for the others.

Dwarf Trees.—See remarks on these last month. Set from 6 to 10 feet apart, according to the shape in which they are to be trained. The union of the stock and tree should be just below the surface.

Blackberries and Raspberries start early, and need early planting. Nurserymen furnish a cane with them, but this is of no use save as a handle. No fruit is to be expected the first year. The canes that grow this year will bear fruit the next. The "Kittatinny" is the best general blackberry. The "Brandywine" and "Highland Hardy" are among the leading hardy raspberries, and Miami or Mammoth Cluster, the best Black-cap.

Gooseberries.—The Downing is the best native.

Currants.—Versailles and White Grape are the best red and white. Black Naples for black. Both gooseberries and currants may be trained to a single stem like a small tree, but the prevalence of the horers make it risky. The better form is an open bush with 4 or 5 stems. Both are sensitive to hot weather, and the ground should be mulched.

Strawberries.—When cold weather is over, part the straw or hay covering over the plants to expose them freely. For varieties and new beds, see p. 102.

Grapes.—Every one who cultivate grapes largely, will have "Fuller's Grape Culturist," or other work, as a guide. The neglect of farmers to grow grapes would be astonishing, did we not consider the great amount of mystery that has been thrown around the training, pruning, and culture generally by some writers. There is no reason why every farmer's family should not have all the grapes they can eat; and there is scarcely a town or village lot so small but at least one vine may be grown.

A Vine can be carried anywhere, almost, so tractable is it. If one has a vineyard, he will follow some regular method. But grapes can be had if there is a fence, a shed, the side of a barn, or that of a house, to train them upon. Fruit may be had within a foot of the ground, or 15 or 20 feet from it. We will talk about training another month.

Plant a Vine or Vines.—Small vines, which will soon become large, may be had by mail. A vine one, or at most two, years old is better than older. You do not want several feet of old cane or vine. You want a good root, with a piece of vine long enough to have about three buds. All the rest is useless. Having a rooted plant like this, consider where you are to run your vine; give it a good, large hole, and if the soil is bad, put in some good, fresh earth. Do not put the roots in a deep hole, but spread evenly, and cover with 6 or 8 inches of earth. If but one can be set, be sure and plant that one. If room for more, and they may be put every 8 or 10 feet, set more. Before planting the vines, put a stake—a pole—6 or 8 ft. or more high, in the place, to avoid injuring the roots by driving it.

When the buds start, there will be 3 or more; rub off all but 2 of the strongest, and when the shoot from either of these is long enough to tie to the stake, tie up the strongest of the two with a soft string, and break away the other. To start right, you must grow but one shoot the first year, and keep that tied up as it grows.

What Varieties to Plant.—It is probably safe to say that the "Concord" will suit the greatest number of localities. "Brighton" and "Creveling" are among the earliest. "Delaware" is a favorite for rich soils. "Barry" and "Wilder" are, with

us, excellent. So much depends upon locality. Have a plenty of the Concord, and find out what other varieties have done well in the vicinity.

Kitchen and Market Garden.

Forwarding plants in hot-beds and cold frames will be the main work this month, except in southern localities, where the planting out and seed-sowing will be going on in some States, while still further south, marketing will have begun.

Hot-Beds and Cold Frames were treated last month as fully as is practicable in a journal. A week's experience with either will teach an intelligent person more than can a volume. In most northern localities, this month will be soon enough to start a hot-bed (see last month for details), or to sow seeds in a cold frame. In an article on page 102, on "Protecting Plants in Spring," we have endeavored to explain the principle of the cold frame. It consists in catching the sun's heat during the day, and before cooling sets in, covering the bed to retain the heat. Judiciously managed, a cold frame will be found of great use, but all

Plants Under Glass need care. The right thing must be done at the right time, or all the labor of weeks may be lost in an hour. Both hot-beds and cold frames must be ventilated, daily, at this season, or, as gardeners say, they must "have air." This is done by lifting the upper end of the sash, and holding it up by a long wedge-shaped block, which will allow the light to be varied, or by sliding down the sash, or even removing it altogether. The sun's heat in a closed bed will soon kill tender plants, and neglecting to close up on a raw and cold afternoon may check and injure the plants beyond all recovery. The care is not much, and may soon become a habit—but it must be given without fail.

Watering must be attended to, and when the soil gets packed and crusted between the rows, break it up or mellow it with the finger, or a pointed stick.

Seedlings, when large enough, transplant to other frames, giving, at least, an inch each way.

Window Boxes, as mentioned last month, will allow the few plants needed for the family garden to be forwarded nearly as well as in a hot-bed. Observe the transplanting. Expose to air whenever the weather is mild, to get strong and stocky plants.

Transplanting to the Open Ground will vary with the locality. Cabbages do not mind cool nights, if well hardened off, while tomatoes are readily injured. See p. 102, on the use of hand-lights.

Plants Wintered in Cold Frames.—The gardeners near New York remove the sashes altogether from their cabbage, lettuce, and other cold-frame plants, early in March, and transplant to the open ground as soon as that can be made ready. They do this both to harden off the plants and to use the glass for

Forwarding Lettuce.—Other frames are made ready, with rich soil, the fall before, and filled with leaves. This month, the leaves are removed, the sashes from the cabbage frames placed on these, until the soil is well warmed, and lettuce plants which were wintered in the other frames are planted in these. For details of this and forwarding cauliflower in the same manner, see Peter Henderson's article "A Double Crop," p. 63, last month.

Preparing the Soil.—Those who failed to take advantage of the favorable weather last autumn to manure and plow, or spade, all vacant ground, made a mistake, and must now wait for suitable weather. Plowing, or otherwise working the soil, is one thing that cannot be hurried without injury. If the soil will not crumble, we must wait.

Sowing Seeds in Open Ground.—Novices often err in sowing many things too early. The old way was to have a time of "making garden," sow pretty much everything at once, and be done with it. The consequence was, a glut of vegetables at midsummer, with a corresponding scarcity early and late. It is of no use to sow seeds of sub-tropical plants in the open ground until the soil gets well warmed, and chilly nights are over; while those natives of temperate regions flourish all the better before the summer's heats come on.

Early Sowings may be made of the following, as soon as the beds can be got ready; the following

to grow where sown: Beet, Carrot, Cress (Pepper-grass), Leek, Onion, Parsley, Parsnip, Peas, Radish, Spinach, and Turnip. Among those to be sown in a seed-bed for transplanting are: Celery, Cabbage, Cauliflower, Kale, and Lettuce. Parsley is often transplanted, and may be included in these. All of the gourd or squash family, all of our garden Beans, Corn, Tomatoes, and others, must be left until warm weather, or else be sown under glass.

A *Seed Drill* is a time—and back—saving contrivance, and will pay even in a moderate-sized garden. They generally are convertible into useful hand cultivators. We have tried only Allen's Planet, Jr., and Comstock's, and would not part with either for many times its cost. These, and no doubt others, are offered in our advertising columns.

Peas should go in early. "Alpha" is a little later than the "Danl. O'Rourke," under its many names, and is the earliest wrinkled pea.

Early Potatoes must be planted early. Where it is not time to plant, bring the seed potatoes to a warm room to start the eyes. We put in the earliest planting as soon as the soil will allow, and keep some litter at hand to pull over the rows, should a frosty night occur after they are up.

Sweet Potatoes are "bedded" in the Southern States early this month, either in a gentle hot-bed, or more frequently on a piece of rich soil, sheltered by a fence, where the sun will lay during the day, and the bed can be covered at night with litter or boards, to retain the heat. In either case, the tubers are laid lengthwise, and covered with rich, light soil. Cotton-seed and castor-pomace have been suggested as heating material for this use.

Asparagus Beds.—Wherever winter is over, rake off the coarse litter, and fork in the fine manure.

Odors and Ends.—Secure pea-brush and hean poles, if not done, before the leaves start.... Order seeds, if not already done.... Have extra hoes, rakes, etc., and extra parts to any machine likely to be broken.... Manure should decompose rapidly now; turn over the heaps, and add water, if at all dry.... Be prepared to meet the "potato hug" on its first appearance. If help is at command, it pays to hand-pick the first comers.

Flower Garden and Lawn.

Tree-planting, so far as deciduous trees go, should be done with the same care as directed for fruit trees. Evergreens may be left until later, and they require even more care, for if the roots once become dry, they cannot be resuscitated.

The *Lawn* must be a remarkable one if a dressing of some kind will not help it. Manure should not be used, unless so thoroughly decomposed that no seeds remain alive. Ashes, guano, or other fertilizers applied to meadow lands may be used here.

New Lawns should have the soil thoroughly prepared and well enriched. Our experience in sowing mixed seeds has not been satisfactory. For a rich, and especially a lime-stone soil, we should sow Kentucky Blue Grass, and for light sandy soils, Red-top, or that variety of it known as "Rhode Island Bent," with, perhaps, a quart of White Clover Seed to each bushel of grass-seed.

Small Plots and Margins of Lawns are best laid with sod. In sodding a plot, make the soil thoroughly fertile, and take care that there are no loose places that will settle.

Walks and Drives can not be permanent and satisfactory without a good foundation of stones at bottom, gradually decreasing in size to the surface.

Clumps of Perennial plants that have been in place for several years may be taken up, divided, and reset in fresh soil. Pæonies and a few others should only be disturbed in autumn.

Beds of Bulbs may be uncovered, and where the weather is not settled, it is well to be prepared to cover the bed if a severe night occurs.

Bedding Designs.—If any are to be planted, they should be well considered beforehand, and have the plants, whether from cuttings or seeds, in course of propagation, and look out for the

Propagation of Geraniums, Verbenas, Chrysanthemums, and other plants for decorating the grounds.

Greenhouse and Window Plants.

The increasing heat of the sun will not only be favorable to flowering, but cause plant enemies of all sorts to propagate rapidly. Regular weekly fumigation with tobacco, when practicable, or if this can not be done, the regular use of tobacco water will keep most insects in check; copious showering kills others, and removes dust.

Airing may be done more freely, and plants should be gradually hardened off to prepare them to go outside later in the season.

Fuchsias and other plants that have been resting during the winter may be started into growth.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our daily record during the year, show at a glance the transactions for the month ending Feb. 12th, 1878, and for the corresponding month last year, and also for the year ending Dec. 31, 1877:

Gold has been up to 102½, and down to 101¼ @ 101½, closing February 12, at 101½, as against 102½ on Jan. 12; 103 on Dec. 12; 102½ on Nov. 12; 103 on Oct. 12; 105½ on July 12; 104½ on June 12; 107½ on May 12; 104½ on March 12; 105½ on Feb. 12, of last year.

Advices from Europe, in the political and commercial lines, have been generally unfavorable to free export purchases of produce. Receipts of Breadstuffs from the interior have been liberal for the season; and the offerings of Flour and Grain in the local market have been, as a rule, in excess of the requirements of buyers, leading to a material decline in prices, in most instances, the market closing irregular. The principal operations for shipment in the Flour line have been in low grade extras, largely of the Minnesota class—and in Wheat, mainly of the best qualities of Winter and Spring, which left off rather more firmly. The Corn movement has been less satisfactory even at the reduced quotations. New York No. 3 grade of the new crop—under the quality of steamer—has attracted more attention. Barley has been fairly active, in good part for export, but at easier prices. State Rye has been more sought after, and has been held with a fair show of confidence. Oats have been depressed and unsettled, on a restricted trade, closing more steadily. Some export purchases of No. 2 Chicago have been made for the French market. Provisions have been fairly active, but hog products further receded in price, leaving off a shade stronger. The export movement has been extensive, largely on through freight account in Bacon and Lard from the West. For British and Continental markets. The better qualities of Butter and Cheese have been quoted firmer, with a good demand noted; poorer qualities generally slow of sale, and weak as to values. Eggs fluctuated widely, but left off somewhat steadier. Hops have been selling quite freely, in good part for shipment, but at somewhat lower rates. Wool has been in comparatively moderate request, and at the close quoted rather weak as to price. Tobacco has been quiet within the previous range. Seeds have been unsettled. Timothy and Flax quiet. Clover fell materially in value near the close, under free offerings, and a moderate inquiry, mostly from shippers. Hay and Straw have been in demand at about previous quotations. Ocean freights have shown less activity, and rates have declined. Grain rates by steam to Liverpool closed on the 12th of Feb. at 90½d.; to Glasgow at 8½d.; to London at 9d.; to Bristol at 10d.; to Hull at 10d.; to the Continent at 9½d.; to Liverpool,

by sail, 7¼@7½d.; London, by sail, 7¼d., ½ bush. Flour to Liverpool, by steam, 3s. 6d.; London, by sail, 2s. 3d., and by steam 3s. 6d. @ 3s. 9d.; Bristol, by steam, 3s. 6d. and sail, 2s. 3d. @ 2s. 6d. per bbl. Provisions by steam to Liverpool, 40s. @ 47s. 6d. per ton; Cotton by sail 1½@ 1½d., and steam at 1½@ 1½d. ½ bush. Grain, by sail, for Cork and orders, at 5s. 6d., and to Continental ports, 5s. 6d.; Italian ports, 5s. 3d. @ 5s. 6d. per quarter; to Lisbon, in ship's bags, 1½d. cts. per bushel; to Oporto, in ship's bags, 20 cts. per bushel.

Bees.—The market has been dull, or worse, all through the month. Every market day, however, has taught the same lesson, viz., that good stock is always salable, and indeed in demand, so that it sells itself in fact, while poor stock drags, and when the market is lifeless must be sacrificed to get rid of it, if indeed it does not pull down better stock with it. The low value of Western dressed beef, which has sold at 50¢. ½ bush. lb., has added to the general slowness of the market. At the close of our report, a loss of ½c. ½ bush. lb. was made from the previous week's prices, and the tone of business was not encouraging. Sales were made at 8½@8¾ for thin steers; 9@9½c. for good native steers 56 lbs to the cwt., and 9½@11½c. for first quality to extra of 57 to 58 lbs. to the cwt. **Cows** have been quiet and steady through the month, sometimes slow and picking up

again without change in prices; a fair test of values is given by a sale of a lot of 16 fair milkers at \$45 to \$50 per head. Poor cows have sold for \$20, and extra at \$90, calves included. **Calves.**—Prime veals have been in good demand, selling quickly at 8½c ½ live weight; poor calves sell slowly at 2¼@2½c. ½ live. Hog-dressed are in light demand, and prices rule low. Sales made at the close were at 10@11c. ½ live for prime; 9@10c. for ordinary; grassers at 5@6c. ½ live. **Sheep and Lambs.**—It is a mistaken policy for farmers to send ewes to market that bring forth lambs in the sale pens. Many such are now arriving, and do not tend to make the stock lively of sale. The market has been dull, but improved toward the close when sheep sold for \$4.50 to \$6.75 per 100 lbs.; dressed mutton brought 7c. to 9c. ½ live, and lambs 6½c. to 7c. ½ live weight. **Swine.**—After a dull market through the month; at the close live hogs were quoted, but not sold, at 4¼@4½c. ½ live; city dressed closed quiet at 5@5½c. ½ live, and light near-by pigs at 5@6c. ½ live dressed weight.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

Publishers' Notices, Terms, etc.—The Annual Subscription Rates of the *American Agriculturist*, postage prepaid by the Publishers, are: One Copy, \$1.00 a year; Two Copies, \$3; Three Copies, \$4.20 (\$1.40 each); Four Copies, \$5.30 (\$1.30 each); Five to Nine Copies, \$1.25 each; Ten to Nineteen Copies, \$1.20 each; Twenty Copies and upwards, \$1.10 each; Single Numbers, 15 cents, post-paid.—The above terms are for the United States and Territories, and British America. To the above add 14 cents extra per year for papers delivered by mail in N. Y. City, and for copies sent outside of the United States and British America, except to Africa, Brazil, British Honduras, the East Indies, and Mexico. For the last named five countries the extra charge is 33 cents per year, to cover extra postage; Single Numbers, 17 cents, post-paid. **Remittances**, payable to Order of Orange Judd Company, may be sent in form of Checks or Drafts on N. Y. City Banks or Bankers; or P. O. Money Orders; or in Registered Letters, such letters to have the money enclosed in the presence of the Postmaster, and his receipt taken for it, and the postage and registering to be put on in stamps. Money remitted in any one of the above three methods is safe against loss. **Bound Volumes** from Vol. 16 to 36 inclusive, supplied at \$2 each, or \$2.50 if to be sent by mail. Sets of numbers sent to the office will be bound in our regular style for 75 cents (30 cents extra if to be returned by mail). Missing numbers for such volumes supplied at 12 cents each.—**Any Numbers** of the paper issued for 21 years past, sent post paid for 15 cents each; or any full year, sent unbound

Good Things Free.

Our Readers are reminded that the valuable assortment of Useful and Desirable Articles, offered in October, are still available to all of them. A few hours, often as many minutes, will secure as many Dollars worth of just what one wants. During every month of MARCH, for many years, Hundreds of our readers have obtained these valuable articles without expense. We can not spare space to give even the catalogue of these articles, but will be happy to send a list, with full description of each article offered, to any and every one desiring it, who will simply give us his or her address by postal card, and say on it, "Send me Illustrated Premium List." Over 20,000 of our readers have received these premium articles with great satisfaction. Thousands may do the same this month.

Important Advertisements. Important especially to all who are on the lookout for seeds, plants, implements, fertilizers, etc., occupy the space always well filled this month. We have tried to admit none but good, trustworthy parties. It is well for every reader, whether in need of anything or not, to carefully go through these business announcements, learn what is offered, by whom, and how it is done. One is likely to get some business hint useful to himself, by seeing what others say, and how they say it. When corresponding with any of these advertisers, sending for their circulars, or otherwise, it is well to let them know that you belong to the great army of intelligent readers of the *American Agriculturist*.

Is Your Life Insured?—Every man having others dependent upon his life, whether his own family, or creditors, or who is liable to have his business or property sacrificed by his death, for want of a little ready money, is in duty bound to make the best provision possible against such contingency. A small sum paid annually for what is termed "life insurance"—a form of expression that is misleading to some minds, for it is really an insurance against a business emergency—will make one's family secure. A man thus provided will be far less worried in sickness, and his chance of recovery will be greatly increased. In this respect, it is life insurance. The failure of some Companies has made the people distrustful of all; but a perusal of the exhibit of the N. Y. Life Ins. Co., on page 109, will show at least one Company where a man can go with the utmost reliance. A request sent to the Company will bring such particulars as any one may desire to obtain.

A Most Desirable Residence, for a well-to-do family, in a delightful New England rural City, with superior advantages for Education, Good Society, etc., is advertised on page 113.

A Book for the Garden.—Probably no Book ever published on garden matters has been so useful, has made so large returns to the purchaser, as "*Gardening for Profit*," by Peter Henderson. It is the first book ever published in this country giving the practice of those who followed gardening for a living. The methods of market-gardeners, who do everything in the best and most economical manner, are generally such as may be profitably adopted by those who raise vegetables for their own use. Gardening for Profit does not necessarily mean market gardening, for one who has only a small private garden wishes to work it most profitably in making it yield the best returns for the least labor. Every one who has a garden, whether he sells produce or not, every villager, and every farmer, who can raise vegetables at all, can not afford to do without "*Gardening for Profit*." Sent from this office, post-paid, for \$1.50.

Gardening in the Country.—A large number of our readers pass the winter in cities, and go to the country for the summer. These wish some work which will tell them something about vegetables, about fruit, and about flowers. Also there are many who live in the country permanently who wish a single book that will cover all these subjects. We know of no Book which will meet the wants of both these classes, as well

as those of rural residents generally, so well as "*Gardening for Pleasure*," by Peter Henderson, which, besides the subjects mentioned, is very full as to parlor and window gardening. Sent, post-paid, for \$1.50.

A Fruit Book for Farmers.—If one is to make fruit culture of any kind an important part of his business, he will, as one of the most profitable investments he can make, procure all the works devoted to the subject. If strawberries, grapes, or other fruits are to be raised for market, he will need the treatises on those special cultures. On the other hand, those who grow fruit mainly for home consumption, and sensibly supply their families with all the kinds that may be readily cultivated, wish to have one book, that will treat sufficiently on all kinds of fruit, and will give them some account of the best varieties with plain directions for their cultivation. Precisely such a work as this is to be found in Barry's "*Fruit Garden*." We have many times regretted that the author choose just this title, as it to many conveys the idea that it is devoted to small fruits, and does not treat of the orchard. There is no other work within our knowledge that so completely meets the wants of the fruit-growing farmer as this. Its distinguishing feature is that it takes the farmer into the nursery, and shows him how fruit trees are, so to speak, made from the raw material, beginning at the very beginning, and taking him through every step, to the picking of the fruit in the orchard, and all told so plainly and minutely, that any one can follow its directions. As with fruit trees, so with all other fruit-bearing plants. We doubt if there is an operation to be performed on fruit trees and plants that is not here clearly described. Grafting, budding, pruning, are all fully illustrated, and it is shown there is no mystery about them—nothing but what any intelligent person may do. Select lists of each kind of fruit for early and late, are given, with sufficient description. Young men who find farm-life monotonous, can find an abundant variety in raising fruit, and we know of no work that is so complete a guide as this. Possibly some may not be aware of the fact that the author is of the great nursery firm of Ellwanger & Barry, Rochester, N. Y., and the same P. Barry, Esq., who is President of the Western N. Y. Horticultural Society, and Chairman of the most important committee of the American Pomological Society. The work is a thick 12mo., of nearly 500 pages, abundantly illustrated, and sent from this office, by mail, for \$2.50.

Important Farm Experiments.

How Every Farmer taking the American Agriculturist, can have an "Experiment Station."—"Science Applied to Farming" by the Farmer Himself.

No intelligent farmer, who cares to increase the yield of his crops, can have read the results of experiments with fertilizers, given by Prof. Atwater last month, on pp. 50 and 51, and this month, on p. 91, without feeling a strong desire to do something of the kind himself. Prof. Atwater, in a private note to the editors says: "If you were to hear some of the farmers talk, who made these experiments last season, you would surely get enthusiastic yourselves."—That we did get "enthusiastic" in our own way, without hearing the "farmers talk," but over the more powerful eloquence of their figures, is shown by an editorial note, "Important Farm Experiment," on p. 49, last month. A letter just at hand from an intelligent correspondent in Somerset Co., N. J., asks our advice, whether a young farmer should become "sufficiently educated in agricultural chemistry, to enable him to analyze his soils, and thus solve the problem:

'What Fertilizer can I Use to the Best Advantage?'

Our reply was in effect: Chemistry will be of great use to him, but not "for the analysis of soils." Chemistry has taught us a better method, and he was referred to Prof. Atwater's article last month. Two or more years ago, in our first account of the Connecticut Agr. Experiment Station, we stated that, though the Station itself was local, its benefits would be widespread and general. There should not only be one Experiment Station in every State, but in some States it would be well to have one in every county. The question of fertilizers is but one of the many that an Experiment Station should work at. Legislative hodies move too slowly, at least in useful directions, and while they are considering, and as often refusing, the establishment of Agricultural Experiment Stations, we propose to establish an

American Agriculturist Experiment Station,

not in this or that State or County, but on every farm in America, where the owner wishes it. That, with the exception of new land, and some specially fertile regions, our soils need, for the best results—for profitable farming—more manure than our farms furnish, requires no argu-

ment. The fact that farmers have expended millions of dollars, in the attempt to supply this deficiency, shows that they know of its existence, and are in earnest in their endeavor to supply it.

But Millions have been Wasted,

or well nigh so, in part, in the purchase of worthless fertilizers, and those in the purchase of good ones—but of the wrong kind. The want of fertilizers being admitted, the next question naturally follows:

"What Fertilizers Shall I Apply?"

Having reached this point, hundreds of farmers every spring and fall write to the *American Agriculturist*, embodying the above question. Here is the great oversight. Instead of asking us, or any other journal; instead of sending a sample of soil for analysis to find out what it lacks—a waste of time and money, as any honest chemist will admit; instead of reading over the certificates of this or that fertilizer, go directly to headquarters, and Ask the Soil Itself, "What Do You Want?"

Among the various projects the *American Agriculturist* has set on foot for the benefit of its readers, none has had more practical value, or will be so far-reaching in results, as the plan we now propose, of enabling the farmer to address the above question to his soil himself, and to show him how to interpret the answers. Those who have read the articles by Prof. Atwater last month and this, will have an idea of what we propose. The questions are to be put directly to the soil, in the form of fertilizers, which present the most essential ingredients, viz., nitrogen, phosphoric acid, potash, sulphuric acid, and lime, in the best forms, both singly, and in various combinations, i. e., these several constituents alone, and in pairs, and all together. To do this satisfactorily, each constituent must be afforded in an available form, and

Of Tested Quality,

in order that the results may have a positive value. Our plan is in brief, this—and it is simply doing on a larger scale—for the country at large—what the Conn. Agr. Experiment Station did last spring—with most beneficent results, for a few farmers in its vicinity. For so doing we are fortunate in having the hearty co-operation of the Mapes Formula and Peruvian Guano Co., with whom arrangements have been made to furnish a series of fertilizers for carrying out experiments such as have been referred to. These will be of the best quality, as shown by analyses by Prof. Atwater, and will be accompanied by full directions for making the experiments, and by blanks for noting the results, so that the latter may be preserved, and the best use made of them. Each article will be put up in quantity proper for one-tenth of an acre. The area recommended for an experiment—an acre—is to be planted with corn, potatoes, or whatever crop may be selected for the experiment, is to be divided into ten equal plots. Provision is made to apply the fertilizers to seven of these plots; the other three of the ten to be on the same crop, but without any fertilizer. The set of experimental fertilizers, A, to be used for this experiment is shown in the table, which indicates by numbers the article to be applied to each plot; the quantity to be applied, the constituent or kind of plant-food it is intended to supply, and finally the cost of each. This "set A" is to be sent complete. The fertilizers will each be put up in a separate bag, and labelled. These small bags will then be enclosed in a larger one, which will also include a pamphlet carefully and especially prepared by Prof. Atwater, giving useful information about fertilizers in general, and about these in particular, and will also give full directions for making these experiments in order that each farmer may best learn what constituents are most needed.

For His Own Soil, and His Own Crops,

and how he may afterwards supply them most economically. The farmer's question to his soil will thus be, "What do you most need that I should give you, in order that you shall give me the best yield of such and such crops?"—The what is to be answered by the experiments with set A. This may be as far as many will care to go in the first experiment. But some will wish to learn also in what form they can purchase nitrogen, phosphoric acid, and potash, most economically for their particular soils and crops, and what ones of the ordinary fertilizers in the market they can use most profitably. The following table of "Extras" shows, as before, the commercial articles that may be used, the quantity for one-tenth of an acre, the important ingredient, and the cost. Set A must be ordered unbroken. Any of the articles, under "Extras," one or more, can be ordered by their numbers at the prices opposite. Individual articles of Set A can be ordered with the Extras at the prices named, provided not less than six in all are ordered together. Suggestions as to the use of these extras will also be given in the pamphlet accompanying the sample.

How to Get the Experimental Fertilizers.

NOTE.—As not one cent of profit accrues to us, and as the enterprise will involve the expense of extra clerks,

etc., we feel that we have a right to ask our friends to make it as simple as possible.

The cost of the Experimental Fertilizers as given for the full Set A, is \$7.00, and must be ordered entire. If one wishes to experiment with the "extras," they must be ordered in the quantities and at the prices named in that table. The cash must in every case accompany the order.

CORRESPONDENCE in relation to these fertilizers should be distinct from everything else. Please observe this. If writing about subscriptions to the *American Agriculturist*, books, or any other matter, to go in the same envelope, put whatever relates to these fertilizers on a separate sheet, with date and address upon it.

When we have transferred the order to the "Mapes Formula and Peruvian Guano Co.," our responsibility ends. They will see to the packing and forwarding.

TRANSPORTATION.—If there is any choice as to route by which the parcels are to be sent, state it plainly on the order, otherwise they will be sent by what seems to be the most direct conveyance.

FINALLY AND PARTICULARLY.—The articles, and only those, in the quantities specified, are to be ordered. Recollect these are *experiments*, made for your own future benefit, and we are not in the fertilizer trade. The prices are fixed to just cover the cost of genuine fertilizers, bags, and putting up, printing, and other incidentals connected with the enterprise, without profit to anybody. It is expected that the increase of crop will, in large part, repay those who use the fertilizers, while the direct information obtained for future guidance in buying and applying fertilizers, will be of immense value. The fertilizers sent out will be such as can be bought of reputable dealers generally, and it may be convenient to many to purchase them, in the quantities advised, nearer home. The only object of arranging to have all these experimental samples sent from a single house, at first, is to secure uniformity, and purity, by having them carefully tested. The Publishers of the *American Agriculturist* receive not a penny direct or indirect, their only part will be to receive and disburse the money as requested by those concerned.

The Strongest Testimonials are constantly coming in from those best able to judge by experience, as to the real value and effectiveness of our Microscope, and its marvelous cheapness. Higher institutions of learning send in for them by the dozen and twenty, to be used by classes in Botany and Natural History. Any one failing to appreciate its value above the cost of both the Journal and the Microscope, has surely failed to use it properly, and should try again after carefully studying the 14-column descriptive sheet and the microscope articles in this paper each month.

A Pupil in Horticulture.—Our Editor, who lives at "The Pines," writes: "For a number of years I have had young men here who were not properly apprentices, and not exactly pupils. A young man of decidedly horticultural tastes can here pick up a knowledge of almost everything relating to horticulture, except such refinements as the culture of stove-plants. To one who is both a student and worker—and it has been my good fortune to have had such heretofore, I can give opportunities for improvement in botany and horticulture. The position will soon be vacant. No pay, and a plenty of work, though the work is largely instructive. Applicants may address "The Pines," 245 Broadway, N. Y., with particulars as to age, previous occupation, etc.

Notes About the Microscope.

Every Subscriber to the *American Agriculturist* for 1878, can have one of our Microscopes delivered free anywhere in the United States, on remitting 55 cents as his share of the cost. The rest is borne by the Publishers.

Turn off the Diaphragm.—It is necessary to repeat:—In beginning to use the Microscope, ALWAYS turn to one side the diaphragm—that is, the rubber plate, with the round hole in it, above the lowest lens. This is only to go between the lenses when one has become skillful in their use, and wishes to examine carefully some very small thing. We hear from a number who have neglected this, and were disappointed at being unable to see clearly any ordinary object, but they were agreeably surprised on using the instrument when this was turned out of the lenses.

Read the 14-Column Descriptive Sheet, which comes around each box that holds the Microscope. We have heard from several who carelessly threw this away, taking it to be only a wrapping paper. One sheet is given with each Microscope, and it is full of important suggestions for those not already very familiar with microscopes. Any one who has lost this sheet, should forward a stamp and his address for another copy, specifying particularly "the 14-column sheet."

"Where is My Microscope?" I sent for it five or six weeks ago.... This is the substance of quite a number of letters. The answer is, in nearly every case, the same, viz.: "It was promptly forwarded to you by express."—We always send them by express, where there is an office of the Adams, American, or United States Express Companies in the town where a subscriber who is to receive one resides. But in many cases they have not been called for at the express office, and small parcels, carried at special rates, are not, as a rule, delivered to residences.—So if any one's expected Microscope has failed to arrive, please call or send for it at the express office.

A Capital Object, to examine now, or at any time, is a U. S. Bill of \$1, or any other size. All Government paper for money is now made at one mill, near Westchester, Pa., which is constantly guarded by officials, night and day. In making this paper, fine shreds of red and blue silk thread are mixed with and dropped upon the pulp. These can be plainly seen with one, two, or three lenses, by reflected light, and they distinguish genuine from counterfeit bills. The different lines, etc., in the engraving of the bills, are a pleasing study under the Microscope, either as a hand-glass or on the Stand.—P. S.—If you have no bills, borrow one for this purpose.

Many Hints, useful as well as interesting, about the Microscope, will be given in successive numbers of this Journal. Note and apply what is said about clover seed on page 103.

To Guard the Eyes.—As previously stated, we tried various plans for shortening the upright rod which supports the lenses. This needs to be 2 inches long to raise the lowest power (upper) lens far enough from the object. But every contrivance of the many suggested would add too much to the expense. It is so often desirable to use the lenses as a hand-glass, that it would not do to put a permanent knob on the top. We find no difficulty, as it is unnecessary to bring the eye quite so near to the lenses, as the top of the upright. Some suggest putting a small cork on the upper end. On page 106 another contrivance is shown.—Mr. J. H. Burnett, of Skaneateles, N. Y., writes: "... I received the *American Agriculturist* Microscope a few days since. It is certainly a very neat and complete little instrument in every particular. Some inexperienced may have expected something as large as a telescope, but to me it is a mystery that you are able to get up so complete an instrument, and send it out at the remarkably low price asked of subscribers. The rubber work is neatly finished, and I know the grinding of the lens is an expensive operation. ... But the object of this letter is to suggest a small cap or ball for the top of the standard.... Having a lathe, I turned a neat little brass cap for the top, tapering the top end of the wire for $\frac{1}{8}$ -inch to slip it on. We think it even adds to the finish, and is not the least in the way. You might suggest topping the wire with gutta percha or sealing wax.... A friend writes me that he is exceedingly anxious to get his *American Agriculturist* Microscope, and try it on a ten-cent piece, and see if it will magnify it up to ten dollars."—[That will be attended to by Congress, perhaps.]

Sleeping Upon Iron.—A reader need not be very old to recollect the cumbersome mahogany bedstead, with its four high posts, and massive headboard. Gradually the posts disappeared, and after a while it was found that in many cases a neat light iron bedstead was preferable to a wooden one. The bed has undergone no less striking changes. It is not long since "feathers"

and "bed" were synonyms, and a family must be poor, indeed, if it did not own its feather-beds. At last considerations not only of health, but of comfort, have driven out feathers, and no one accustomed to a mattress of curled hair for a few weeks would return to feathers. But everyone could not afford curled hair, and numerous have been the substitutes. Southern "moss," sponge, palm-leaf, corn-husks, (not a bad substitute if prepared at home, but miserable if done at the factory), and various other materials down to wood shavings and straw have been used. At last, some one hit upon—of all things in the world, the most unpromising for a bed—iron. There are now offered iron—or iron wire—mattresses of various kinds. One that we have had in use for some months is made by the "National Wire Mattress Co., New Britain, Conn." The makers claim that "it can not sag." We know that it has not sagged, and that it is as elastic and pleasant as one could wish. With a foundation of this kind, the mattress, or bed alone, is of much less consequence, than with the old styles. The wire mattress referred to has the merit of being packed into a small space, and is so simple that any one may set it up. After a trial of several months, we are quite satisfied that it combines many useful qualities, including comfort and cleanliness. Its appearance when set up is shown by the engraving on the last cover page of this number.

Sales of Poland-China Swine.—

D. M. Magie & Co., Oxford, Ohio, report sales of pigs for 1877 as follows:—January, 35; February, 34; March, 20; April, 7; May, 21; June, 62; July, 113; August, 43; Sept., 37; Oct., 41; Nov., 50; Dec., 43. Total, 511.

Books for Poultrymen.—"C. S. M.,"

Effingham, N. H. For beginners in the poultry business some useful hints may be gathered from "An Egg Farm," by H. H. Stoddard, (price 75c.), and the "Poultry Farm and Market," by Prof. Corbett, (price 75c.). These books are sent post-paid from this office, on receipt of the price.

Preserve the Numbers.—The numbers of this Journal during a year, bound, or stitched together, make a good-size double-quarto Volume, the reading matter of which would make many \$1.50 books in ordinary book type. There are at least 600 larger and smaller engravings. With index supplied in December, it is easy to refer to any desired topic or article. Mr. Sam'l Smythe, of Pittston, Pa., writes similarly to many others:—"I have taken the *American Agriculturist* ten years, and always carefully preserve and bind the numbers. Nothing else in the house so much interests visitors, as well as members of my own family, as these bound volumes of the *American Agriculturist*."

Pringle's New Wheats.—In an item

last month, we omitted to say that these very promising wheats were offered by Messrs. B. K. Bliss & Sons, but their advertisement was so conspicuous that those interested can have hardly failed to see it.

Good News for Long Island Farmers and Gardeners.—Long Island is one of the

great market gardens that supply New York City. Much of its soil is warm, light, and well adapted to raising farm and garden "truck." The breezes from the south, coming over the Gulf Stream, temper its climate, and even the northern winds are more or less modified in passing over Long Island Sound. The western end of the island, as far out as can be connected with the New York market by a day's wagoning, has long been a great market garden. The long lines of market wagons bound towards New York every evening, and during the night, and homeward bound during the forenoon, have been a striking feature on the roads of the island. The expenses for teams, wagons, drivers, and tolls on roads and ferries, have been a heavy draft upon the profits of the producers—expenses which are now in a way to be greatly lessened. Thanks to the enterprise and public spirit of such men as Conrad Poppenhansen, and others, Long Island is thoroughly intersected by railroads. A circular recently issued by Sam'l. Spencer, Esq., General Supt. of the railroads, addressed to Truck Farmers and Dealers, announces that during the coming season "Prompt and fast Freight Trains, at satisfactory Freight Rates will be run. At such hours as will best suit the requirements of shippers, and of the market dealers. Truck gathered one day can be shipped to market that night, and if necessary, trains will be stopped at other than the regular stations to receive the freight of those shippers who would otherwise be subjected to long hauls to depots. Arrangements have also been perfected for the delivering in market of shipments from parties that may not have provided such facilities for themselves. It is the intention of the Management to offer every possible convenience to shippers." Here is a corporation with a soul! What do our Western friends, who have so strongly, and often justly complained of the arbitrary rules of their railroads, think of this? But better still; Sam'l. Spencer, Esq., does not

claim that he "knows it all," for he says: "It is the intention of the Management to offer every possible convenience to Shippers, and correspondence is invited on this subject, or any other affecting the joint interest of the road and its patrons." Mr. Spencer's address is Long Island City, N. Y. This arrangement will bring the central, and even the eastern part of the island into easy and cheap communication with the New York markets, and make a great saving, not only of horse-flesh, but of human flesh and health, as it will do away with much of the tedious night travel. The practical good sense shown in the management of the railroads by Receiver Sharp and Sup't. Spencer, are a guarantee that the above arrangement will meet the wishes of farmers. The interests of a railroad and its patrons are always *mutual*; in too many cases this fact is ignored by "officials," resulting in dissatisfaction, and injury to both interests.

Silver-Plated Ware.—Numerous inquiries have come concerning the plated wares advertised in our columns, and we have received a few letters censuring us for advertising them at all. If any one is foolish enough to suppose that he will get *silver* when *plated* ware is advertised, we cannot help him. These wares are, as distinctly as the English language will allow, offered as *plated*. After we depart from solid silver, whether "coin silver," or "English sterling silver," we must have plate, and the real value of that plate must depend upon the honesty of the manufacturer. Plated teaspoons, for instance, may be offered at \$6, \$5, \$4, \$3, \$2, \$1, the set of half dozen, and each be good of its kind, and each well worth its cost. The great majority of the users of spoons and forks in the world, use plated spoons and forks, and when we assure ourselves that those who advertise these plated articles will give *the best possible for the money*, that they are men whose word is to be taken, we feel that it is better for our readers to buy articles which will be exactly as they are represented, than to purchase them here and there, with no one responsible for their quality. We can assure our readers that none of those who advertise plated-ware will give them solid silver; and we can also assure them that we have examined the ware, and are convinced that those who buy their plate of those who advertise with us, as Stevens Brothers & Co., and others, will get as good as can be bought anywhere *for the price*. We know of no law which will oblige people to buy plated-ware.

Sale of Choice Jersey and Ayrshire Cattle.—We are informed that Mr. Wm. Crozier, of Northport, Long Island, N. Y., contemplates a public sale of his valuable stock of finely-bred Jersey and Ayrshire cattle, Southdown sheep, and Berkshire swine, on the 10th of April next, at his farm, near Northport. To facilitate access to the farm, the Long Island R. R. Co. will carry passengers at half usual rates, and run a special return train after the sale. A favorable opportunity will here be offered to procure, at reasonable prices, some of the best imported and home-bred stock. A notice of the sale appears elsewhere.

The Poland-China Swine in England.—We are informed that the Poland-China swine sent to England by Mr. Magic, of Oxford, Ohio, the originator of this breed, have been received with much satisfaction by the purchaser, Mr. Munson. This gentleman writes that he thinks these swine are the finest of any in England; he is a breeder of Berkshires, Yorkshires, and Windsors, all of which are cast into the shade by the American pigs. This is another intimation that the opinion we have often expressed as to the excellence of American bred stock of nearly all kinds, is well founded.

Pampas Rice.—Some persons who last year advertised "Pampas Rice," did not like it at all because from their engraving and description we inferred that their so-called "Rice" was only the "Durra Corn," *Sorghum vulgare*, which was described and figured in February of last year. A person in Montour Co., Pa., evidently does not read the *American Agriculturist*, for he sends a circular of the "Pampas Rice," some specimens of the grain, and wishes to know our terms for advertising it. The grain sent proves the accuracy of our conjecture, for it is the seed of the "Durra Corn," and nothing else. Now, we have not the least objections to the cultivation of "Durra Corn." Both the grains and the stalks may be very useful, and it may be that it will be found to have been too much neglected; but let us be truthful, and call things by their right names. As "Durra," and other names given in the article referred to, this has been cultivated in the old world for centuries, and was known in this country last century. Then why call it "Pampas," or any other "Rice." It is not at all related to rice, except that both are grasses, and the grain is not near so much like rice in appearance as the "Rice Pon-Corn." Why say it is of "South American origin," when it was in common use in Africa and Asia, long before Columbus engaged in the ferry business. Gentle-

men in Pennsylvania, Tennessee, Michigan, and elsewhere, bring on all the new grains and plants you can get hold of. If useful, we will help make them known, but we shall insist that old and well known things shall not be rechristened, but that they be offered under their proper names. Farmers, whatever the grain may be, the name "Pampas Rice" is a miserable alias, a fraud.

Easy Churning.—"L. S. S.," Delaware Co., N. Y., writes that "the difficulty in churning and bringing butter late in the season, especially with the cream from one cow, can be obviated by a very simple process, viz.: after the milk is strained, set the pans on the kitchen stove and scald the milk, which will cause the cream to rise in a much shorter time, and if it is of a proper temperature, it will churn and bring the butter in from 5 to 10 minutes, of a better quality, and entirely free from any bitter or unpleasant taste."

A Manure Club.—"A. B. S.," Bucks Co., Pa. We fear the cost of transportation of manure from New York to Bucks Co., would be too great for profitable purchase from the street-car companies. If the manure was baled, the carriage would be easier. The 2d, 3d, 4th, 6th, 7th and 8th Avenue are the largest car companies in New York. It is sufficient to address either of these by their title at the City of New York.

Sundry Humbugs.

We take up our budget of Humbugs—what a heap it is that collects in a month! There are letters from correspondents, bits cut from papers all over the country, memoranda made as things have turned up, and notes of information that we get from—but we don't propose to tell all of our sources of information. Some people would "peel their eyes," did they only know the how. Well, we take up this formidable parcel, and assort it—Lotteries in one place, "Queer" in another pile; "Oil Paintings" make a pile, "Medical Matters" another, and so on through the heap. The size of these

parcels afford a fair indication of the run of a particular scheme. We at first thought that the largest pile belonged to the "Oil Painting" affair, but as Irving's

DUTCH JUSTICE,

was it *Wouter Von Twiller*? weighed the law in the case, by balancing a law-book in each hand, we find that the lottery swindle—"A Decision at Last"—is a little the heftiest. This is the concern which proposes to settle up defunct lotteries by making new drawings, and they give orders on Russell & Co. for Gold Watches and Chains, and no end of Jewels. We are so tired of this thing; and yet the circulars will come piling in by the bushel! We would gladly let this thing drop, but when we get letters, like the one before us, evidently written by an educated person, who signs himself (giving, of course, being a gentleman, his real name, also,) "A Reader of Your Paper," we wonder, really, if it does any good to expose humbugs. What can

THIS READER HAVE READ?

when for the last several months we have been obliged to give special prominence to the "Decision at Last" fraud, with Russell & Co. as executors? If anything has been set forth, ventilated, and warned against, it has been this, but yet these come—several this month, persons as innocent as can be, and ask about it in all sincerity... Here is a letter enclosing one of the "Decisions at Last" circulars, from Sharon, Pa. The writer, who is entitled to a lot of jewelry, wishes us to go to Bond street, and see if they will not change the jewelry for "a part watches," yet this very man claims to have read the Humbug articles. Do people comprehend what they read?... It is refreshing to get hold of a new swindle, but here is one that is such a miserable imitation for the foregoing, that we are tempted to think it is the same old Topeka thing, under a new name. Its circulars are headed

"CONSOLIDATION OF ALL THE LOTTERIES,"

the same old story about "unsettled prizes," and a "Committee," and a new "drawing." The orders are not upon Russell & Co., but upon J. S. Blanck & Co., Broadway, N. Y. Gold watches and chains have fallen; this scheme values them at only \$40—a base imitation. "Blanck" is a good name to use with this.

"THAT ROYAL DOMINION GIFT CONCERT,"

at St. Stephen, New Brunswick, continues to send its

schemes all over the States, and is getting to be more and more of a nuisance. Its manifestoes are more flaring than before, and include

A BAREFACED LIE,

as they print in conspicuous type, "Money can be sent by mail legally," which, as an abstract statement, is true, but it can not be sent "legally" to help any such swindles as this "Royal" one, and postmasters in the United States have not only the right, but are by law obliged, to stop any letters sent to this and similar concerns.

CHEAP JEWELRY.

Here is a letter that serves as a specimen of many. It encloses an advertisement of what is called jewelry. The writer, in Canada, wishes our opinion, but as he enclosed no postage, he did not get it. He says, "You will understand my question—is it a humbug." The advertisement contains several "lots." The first is a "50-cent Lot;" it offers a Watch Chain, a pair of Sleeve Buttons, a Stone-Set Searf Pin, three Spiral Shirt Studs, one Collar Button, and one Wedding Ring—six articles in nine pieces—just 5½ cents a piece. If our correspondent will think of the matter, he will admit that the advertisers do business to make money, and that their "goods" did not cost them anything like what they ask for them—now what does he, or any one else, want with a "wedding ring," or any of the rest, that the seller values at only 5½ cents, and which, probably, did not cost half that to make. If he thinks they are worth any more than is asked for them, let him buy and try.... A recent plant humbug is

"THE CINNAMON VINE,"

advertised by a party in Wayne Co., N. Y., who, we are sorry to say, also advertises the *American Agriculturist* along with books, groceries, and other merchandise. We know nothing of the party; he can buy the *American Agriculturist* as he can coal or gold, or other staple article, and sell it in the same shop with his other wares, and we are in no manner connected with, or responsible, for it. We hold that any one who knowingly sells a well known plant under a new name, and one that does not belong to it, commits a fraud upon the purchaser. In this case, the humbug does not consist in the plant itself, but in putting it out under false pretences. The so-called "Cinnamon Vine" is nothing more nor less than the old

CHINESE YAM, (*Dioscorea Batatas*),

which has been so long known under its proper name. We have often spoken of its utility as an ornamental climber, whatever may be its merits as a food-plant. It has good foliage, and when the plant gets old enough it produces small flowers with a pleasant cinnamon-like fragrance. It is simply an imposition to offer it under any other than its own name.... The "Weekly Visitor," Galveston, Texas, goes for that

U. S. SECRET SERVICE COMPANY

in a most lively manner. We are glad of a coadjutor in the "Lone Star State," and hope he will continue to do so—but that "Secret Service Co." is defunct. One Cincinnati humbug the less, but there is "a few more left of the same sort."

FARMERS MUST LOOK OUT

for seed and nursery swindles, which appear every spring, and of which there promises to be an unusual crop this year. If a concern writes that they have "no time to talk with customers," but do all their business by correspondence by letter—just let them alone, and buy of people whose names are in the directory, and who can be found when wanted. See article on "New and Wonderful Seeds," on p. 100... Having to do with humbugs is not calculated to give one a view of

HUMAN NATURE IN ITS BEST ASPECTS.

Money-making—or more properly money-getting, is at the bottom of all the many schemes, and whether it is to recover an ancestral estate, or to cure some inherited disease, the low aim of mere gain is always manifest, and the operators are "of the earth earthy." Imagine how welcome the change, when we found one letter at

ONLY SECOND HAND FROM THE SPIRITS.

Now there are people who do not believe in spirits, and spiritism, and mediums, and things. It makes no difference what may be proposed, in proof that spirits in the other world find their highest enjoyment in visiting close-chambers in tenement houses in this; tipping over the already rickety furniture, hanging tamborines and—when very jolly, in slapping the faces of people in the dark—still there are people who don't believe in them. Moreover, they ill naturally say that the spirits always foretell that which has happened. Now we have a document that is calculated to silence these hard-hearted persons. It comes from one Reno—who is a "Prof." and he lives in New York, at No. 205 —, but these are not advertising columns. It has a greasy look generally, being written on manifold paper. Some unbelievers may say that this is in order to send several copies of the same "revelation" to different persons, but as we have but two copies thus far, and the date is filled in with blue pencil,

we pass that by with contempt. Reno is a "Professor in Spiritualism," so he says, he holds weekly meetings of eminent spiritualists, he has a medium—and we will let him tell the rest of it in his own way:

THUS WRITES PROFESSOR RENO.

"In our last meeting our somnambulist medium, to our great astonishment, acted in a very strange and refractory manner, and only by the most stringent coercion could be brought to tell that she was influenced by a strange spirit, who tried to induce her to follow him to a certain distance, his object being to reveal a certain hidden treasure which he once got in his possession through a most hideous crime, but being haunted and chased by the officers of justice, hid the treasure, but had in his attempt to escape left the hidden place a dead secret. This he claimed allowed him no rest until the treasure should be unearthed, which we were willing to do, but he objected, saying: 'Only the man on whose property the treasure is hidden shall raise it.' There and then, through our medium, revealed your name and address, and he in spirit showed the exact place the treasure is hidden, and enjoined her that she should in my company show the place to you in person. We asked for further particulars, and he requested us to inform you of this, and you would send the necessary traveling expenses, and give us one-fourth of the value of the hidden treasure. After this the medium awakened from her somnambulist state. I now consider it my most imperative duty to inform you of this, and leave it to your own judgment to act in the matter as you please. We are naturally very anxious to secure our share of the treasure, and enjoy you to take the matter in hand at once, and forward \$25, the necessary traveling expenses; and when you send the above amount, send only by letter. Address, etc."

It all went very well until we got towards the end, and then our faith in spirits and professors of spiritualism got shaky, and we lost faith, just as the poor child did when she found her doll stuffed with saw-dust—"Forward \$25!"—the "spirits" are as bad as embodied humbugs.

MATTERS AND THINGS IN BRIEF.

"THE QUEER," or counterfeit money fraud though subsidized, is by no means dead; we have perhaps one new phase of it a month, while formerly there were 20 or more. We have said little about it of late, as it can harm no honest person. Frank A. Johnson sends out circulars in which he offers his as "cigars." Take care, Frank, a cigar has one end that burns. We would say to those good people who, astounded at receiving a proposition to purchase counterfeit money, propose to us a plan to catch the chaps, that it will do no good. They have no counterfeit money, and can not be troubled for offering what does not exist. We have some curious developments in the NOTE BUSINESS—farmers, and all others, be careful what you sign. Here is one who wants our opinion about \$3 watches. We guess they are worth about the same price as hard clams—say 50c. a peck. A friend sends a prospectus of a book called the COMPLETE HERBALIST, by one O. Phelps Brown, and asks our opinion. According to the circular it is the "teachingest" sort of a book. When we read of this book that "It teaches, by beautiful engravings, the exact similarity in shape, which exists between medical plants used for the cure of certain organic diseases and the organs themselves," we stop and say bosh! Brown should have lived some centuries ago when people believed in signatures—he is out of place in this age. Medical matters must go over to another month. The ass who sends long anonymous letters about a certain class of medical matters, is advised to save his post-stamps.

A new Industry for the South.—

It would be strange, indeed, if the rich soil and fine climate of the Southern States should be fitted for the production of one staple article only, viz. cotton. The fact is that the Southern States will in time become the richest portion of the country, agriculturally, because of the great diversity of products possible. A new opening has been found for enterprise, viz.: the production of winter butter, and we learn that one farmer of Tennessee, and another of Arkansas, are sending fresh grass butter to Boston market this winter. These farmers keep Jersey cows, which pasture during the winter upon the native grasses, of which Blue Grass is the chief. Blue Grass for winter pasture, and Bermuda Grass for the summer, will sustain cows in fine order, and there is the whole winter for the production of butter. Why should not southern farmers avail themselves of the advantages of their climate and raise dairy products at the time when northern dairies are suspending operations?

Kerosene Oil for Sheep Scab.—"J. W. D., Limestone, Texas. It would not be advisable to pour kerosene oil along the spine of a sheep to cure the scab; the effect would be to cause sores where it was applied, and it would fail to reach the vermin beneath the scabs. As a necessary preliminary to the successful application of any remedy, the scabs must be broken so

that the insects may be exposed to the action of the remedy used. In using any dip whatever, this must be done. A rough corn cob is useful to effect the rupture and removal of the scabs. If it is desired to use kerosene oil, we would suggest that it be poured upon the scabby parts of the skin, and that these be rubbed with a corn cob or something rough—a cattle card might answer the purpose—and the oil made to penetrate to the bottom of the scab. The application should be repeated to destroy the mites hatched from eggs that have escaped. When a dip is used, the temperature should be 120 degrees, as the heat greatly helps the effect of the application.

Breaking a Colt.—"J. P. M., Somerville, N. J. A vigorous colt 2½ years old, may be safely broken to the saddle. At this age hundreds of English horses are not only broken, but are put through a severe course of training, and work on the race-course. One of the most popular races is only open to 2-year-olds.

Roots Flavoring Milk.—"M., Morris Co., N. J. Mangels and other roots will flavor cows' milk, unless they are fed at the milking time. If fed then, the volatile odor and taste passes off through the skin before the next milking time.

Jersey and Guernsey Cattle.—"S. C. D., Moorestown, N. J. The Guernsey cattle have not been bred so much for fancy points or beauty as the Jerseys, and they are consequently, on the average, better butter cows—that is, a herd of ten Guernsey cows, promiscuously gathered, would probably yield more butter in a given time than ten unselected Jerseys. The Jerseys have no doubt suffered from the fashion of breeding for color and points, which has been rife of late years, and there is no doubt that first-class butter cows are more plentiful in Guernsey than in Jersey.

How to Apply Lime.—"Enquirer."

There is but one profitable way to apply lime to land that needs it, and that is to scatter it upon the surface, in an air-slaked or dry, powdered, condition. This may be done in the fall or early in the spring. It will be a waste of labor, and a loss of manure, (not of lime), to compost the lime with manure. There is enough hard work to be done upon the farm, without making useless labor by devising unheard of methods of doing simple things.

The Business of Sheep Raising.

—"J. W. B., New Orleans, La. It by no means follows that any amount of money can make sheep raising profitable. On the contrary, the more money invested when there is no experience, the greater risk there is of loss. Where a person knows nothing about sheep, he had better not invest money in the business until he has learned something about them in a practical way, either by living for a time with a shepherd who knows his business, or by hiring a competent shepherd from whom he may learn.

Southern Agriculture.—The Department of Agriculture of the State of Georgia has issued an interesting report, giving a comparative total yield of crops, with cost and profit, under different systems of labor. In this report is also given a statement of the general condition of farming in Georgia, of which a very good idea may be gained from the following extract:

"there seems to be a tendency on the part of farmers, generally, to change their programme. Their wheat fields had their attention earlier than usual this season; they are raising more potatoes and root crops for stock, and investing their little surplusage in improved fruit. Our county has largely patronized the Atlanta and Augusta nurseries the past season. Improved stock is sought by almost every one. We are paying more attention to our compost heaps, and there is manifested a greater disposition to improve farms than formerly." With such a spirit as this abroad, Southern agriculture cannot fail very soon to become flourishing and profitable.

Seeding with Buckwheat.—"S."

Clover may be sown with buckwheat early in July with success. But it would not be advisable to cut the buckwheat when in blossom and leave it upon the ground for a mulch. By the time the buckwheat is ripe, the danger from heat and dry weather will have passed away.

"Brazilian Artichokes."—The mention of artichokes, especially the variety to which the name "Brazilian" has been applied by Mr. Cohurn in his excellent and popular work on "Swine Husbandry," has caused numerous inquiries as to this variety. There are several varieties of the common Jerusalem Artichoke; there are those with white, red, and yellow skin, and of each of these there are forms with long and roundish tubers. The term "Brazilian" has been applied by some western growers to a variety that produces a rounded, red-skinned tuber; very productive, and does

not spread so much as the common sorts. It is a convenient distinguishing name for the variety, but no more indicates that it came from Brazil than the name Jerusalem does that the common form come from that city, or that Irish potatoes originated in Ireland. Those who have them for sale should advertise, as we have inquiries.

Cultivation of Lucern or Alfalfa.

—"G. W. F., Waynesburg, Ohio. Lucern, or as it is called in California, "Alfalfa," can not be cultivated profitably where red clover will thrive. It is a plant suited for a dry climate, and is a very valuable fodder plant, but clover surpasses it in value and in ease of cultivation. Where heavy liquid manuring could be given, or the crop could be irrigated, it would give a greater yield than clover. We have tried it, but do not care to repeat the experiment. We are satisfied with red clover.

Grinding Bone.—"R. E. C."

If a sufficient quantity of bone can be procured and used to pay for the use of a mill, it would certainly be desirable to work up all the bones for fertilizers that a district could furnish. The Bogardus "Eccentric Mill" is an excellent machine for grinding bones into fine flour, and can be worked by a 6-horse power engine. There are other mills suitable for this purpose, mentioned in the advertising columns. It is not necessary to make fine ground bone into superphosphate, as it is valuable in its raw state.

Endless Chain Dog-Power.—"A. S. S., Portage Co., Ohio.

There are several small tread-powers made for a sheep, calf, or dog, on the same principle as the horse-powers. These cost about \$25. The New York Plow Co., of New York City, exhibited a very good one at the recent American Institute Fair.

Pipes for Conveying Water.—"Subscriber," Lynnfield, Mass.

It is practicable to convey water 2,300 feet from a reservoir with a fall of 30 feet, so as to have the water rise at the outlet to within a foot or two of the level of the reservoir, and escape freely. The first 1,000 feet should be a 1½-inch pipe, the second 1,000 may be 1 inch, and the last 300 feet may be ¾ or ½ inch. Galvanized iron pipe would be best. If a large flow is desired from the outlet, the pipe may be wholly of 1½ inch.

What Proportion of Eggs hatch after shipment.—"R."

If eggs that are shipped by railroad are properly packed and are not too stale, we should expect that as large a proportion would hatch as of any others. We have hatched eggs that have been shipped in barrels 1,500 miles without any unusual loss.

Varnished Cloth as a Substitute for Glass, to cover hot-beds and cold frames.

In February, 1874, we published an article by that wide-awake horticulturist, the late J. B. Root, of Rockford, Ill., in which he gave directions for preparing sheeting as a substitute for glass. He had his sheeting sewed together and hemmed, of a size corresponding to four hot-bed sashes. He melted together, in an iron kettle, Linseed Oil, 1 quart; Sugar of Lead and Rosin, in fine powder, 1 ounce of each. When thoroughly melted and incorporated, he applied this, hot, with a brush, to the cloth, stretched for the purpose on a frame. In two days, he gave another coat. When dry, he used this to cover his frames. No doubt a frame, covered with this—as a shelter—would be a great help, but it is in no respect equal to glass, and as it will, no doubt, shut out at least half of the light, it cannot be used as a substitute.

Basket Items continued on page 113.

Catalogues Received.

See page 8 in January last for other catalogues. SEEDSMEN.

Some of our seedsmen append to their seed catalogues lists of small fruits, greenhouse and hedging plants, etc. And we may say that they, at any rate those in the cities and large towns, keep on sale implements, fertilizers, haskets, aquaria, and all such articles.

R. H. ALLEN & Co., 189 and 191 Water St., N. Y. This catalogue, while not neglecting garden and flower seeds, is especially full in field and farm seeds, novelties in the way of fodder and root crops and grasses.

BENSON, BUREE & Co., No. 223 Church St., Philadelphia, Pa.—Garden, field, and flower seeds, with interesting novelties in each. They are also engaged in live stock of all kinds.

HUGO BEYER, New London, Henry Co., Iowa, offers vegetable and flower seeds "grown in" and for the West. The preface shows that his heart is in his business.

B. K. BLISS & SONS, No. 34 Barclay St., New York.—An enormous treatise of over 200 pages, including everything in their line. Also a special list of novelties.

WM. E. BOWDITCH, No. 645 Warren St., Boston, Mass.—To his general catalogue of vegetable and flower seeds are added one of plants, and lists of later novelties.

D. C. BRAINERD, Mount Lebanon, N. Y., has a handsomely illustrated catalogue of "Shakers" seeds, made additionally useful by an Almanac and Rural Register.

ALFRED BRIDGEMAN, No. 876 Broadway, New York.—Probably no name, except that of Thorburn, is more thoroughly identified with New York horticulture. Mr. B.'s catalogue is, as usual, neat, and up to the time.

W. H. CARSON, No. 125 Chambers St., N. Y.—The excellent taste and neatness of this catalogue, which includes specialties, are characteristic of the author, than whom we know of no more competent seedsman.

JOHN LEWIS CHILD, Queens, N. Y.—One need not be troubled about prices, as all seeds are put up in "Half Dime Packets."

HENRY E. CHITTY, 169 Main St., Paterson, N. J., offers flower seeds in collections at low rates, and the same with greenhouse plants.

COLE & BROTHER, Pella, Iowa, we judge are prospering, as this year's catalogue is a great improvement on former ones. To induce people to buy their seeds, which are largely grown by themselves, they offer the *American Agriculturist* as a premium on easy terms.

COMSTOCK, FERRE & CO., Wethersfield, Conn., include an almanac and useful calendar in their catalogue. The name is so thoroughly identified with the best of Connecticut seeds, that we need add nothing more.

O. M. CROSBY & GORDEN, Danbury, Conn.—The sight of the address brought to mind the "Danbury News Man," who writes a preface to the catalogue, but it is sensible enough to stand on its own merits.

FERRIS, MINARD & CO., Poughkeepsie, N. Y., offer among their vegetable and flower seeds, several novelties, besides various things needed by the gardener and rural resident.

D. M. FERRY & CO., Detroit, Mich., take pride in the fact that their beautiful "Seed Annual" is a "Michigan production." With abundant other illustrations, they give interesting scenes on their seed farm, and a fine colored plate of a "New Dwarf Japanese Cockscomb."

J. A. FOOTE, 512 Main St., Terre Haute, Ind.—Has a full list of vegetable seeds, and among them some excellent specialties, such as the "Terre Haute Nutmeg Melon," which we know to be good. "Green Fringed Lettuce," etc. Also flower seeds and plants.

JAMES J. H. GREGORY, introducer of the Hubbard Squash, sends from Marblehead, Mass., his catalogue, so unlike all others in form and contents, that it is always a pleasure to get it, and to read of the novelties and specialties—but he does not forget the old stand-bys.

R. D. HAWLEY, 492-493 Main St., Hartford, Conn., sends his catalogue of Wethersfield garden and field seeds, and offers a large number of useful implements.

PETER HENDERSON & CO., No. 35 Cortlandt St., N. Y., present in their catalogue in hold letters, "Everything for the Garden," and when we look at its contents we are forced to admit that well nigh "everything," except sunshine and rain, and other unobtainable things, is to be found among their novelties and regular stock.

HOLLISTER, CARTER & CO., St. Paul, Minn., offer a select list of field, and garden seeds, largely grown by themselves. Also sorghum machinery and implements.

A. HOWARD & CO., Pontiac, Ill., flower and garden seeds, a selection of plants, and useful cultural directions.

CHARLES F. LANE, Koshkonong, Wis., has a remarkably full catalogue, largely filled with cultural directions. Also requisites for the apiary, implements, books, etc.

NANZ & NEUNER forgot to say so, on their title page, but we have every reason to believe that they are at Louisville, Ky., and they offer so large a list of both seeds and plants, that we are at a loss to classify their catalogue, which is very full, including novelties in both.

PRICE & KNICKERBOCKER, 80 State St., Albany, N. Y., full, neat, and well illustrated list. They do not need to announce themselves as "successors to," any one. A "Knickerböcker" should be at home in Albany, if any where.

W. H. REID, Rochester, N. Y., sends a well illustrated catalogue, with colored frontispiece, as "Reid's Illustrated Floral Triphart for 1878."

R. M. SHUMWAY, Rockford, Ill., has a catalogue, amply illustrated, and with very full cultural directions, which must be very useful.

H. N. SMITH, South Sudbury, Mass., offers certain flower seeds in collections at very low rates.

THE PLANT SEED COMPANY, (what an appropriate combination of names), St. Louis, Mo., have a catalogue as large, as full, and as amply illustrated as in former years—and that is all we need say.

J. M. THORNBURN & CO., No. 15 John St., N. Y. This is the oldest seed house in New York, and does an immense business in the quietest manner. This year's catalogue is a departure from former years, in as much as they include garden and field seed, flower seeds, and spring bulbs in one neat and comprehensive list, which of course includes "novelties" of the year.

ISAAC F. TILLINGHAST, Factoryville, Wyoming Co., Pa., with a general stock, offers a number of specialties, particularly among potatoes.

VANCEBILT BROTHERS, No. 23 Fulton St., N. Y., a condensed list, offering a full assortment in all departments, including machinery.

JAMES VIEK, Rochester, N. Y., in his "Catalogue and Floral Guide," presents the same abundance of illustration, and neatness, as formerly, and he does not forget the old standard varieties in offering his novelties.

W. C. WILSON & CO., 45 West 14th St., N. Y., well known dealers in plants, now offer seeds, gladioluses, and other spring bulbs, in a catalogue "as neat as a new pin."

DAVID R. WOOD, Morrisville, Lamolille Co., Vt. Vegetable seeds, seed potatoes as a specialty, and the Arnold Poison Distributor first figured by us in August, 1876.

E. WYMAN, JR., Rockford, Ill., gives special prominence to flower seeds and summer-flowering bulbs, and offers vegetable seeds in collections at low rates.

FLORISTS.

Where are they? we have, thus far, save those noted in January, received but a few catalogues in this department—the rest no doubt will come next month.

BENJ. A. ELLIOTT & CO., 114 Market St., Pittsburgh, Pa., calls his catalogue "The Garden." It is largely occupied by useful directions for cultivation, and also gives a list of new and old plants.

ELLWANGER & BARRY, Rochester, N. Y., in their Catalogue of Greenhouse and Bedding plants, have various novelties, including the new Coleus figured last month.

PETER HENDERSON, 35 Cortlandt St., N. Y., prefaces his catalogue with a splendid chromo-lithograph of that fine new Hydrangea, "Thomas Hogg,"—and the white Tea Rose "Corolla Cook."—His catalogue, as usual, presents the novelties of the season, and all those which have ceased to be novelties.

C. H. HOVEY & CO., No. 22 Tremont St., Boston, under the Boston Museum, floral decoration a specialty.

GEORGE SUEH, South Amboy, N. J., in his spring catalogue, makes a specialty of gladioli, but if there is any novelty of the season that is not included in it, we have failed to discover it—and so neat!

A. WHITCOMB, Lawrence, Kas.—A well selected stock of bedding and greenhouse plants, presented in a catalogue which is a marvel of neatness.

J. C. WOOD & BROTHER, Fishkill, Dutchess Co., N. Y., offer a full catalogue of greenhouse, stove, and bedding plants, including the novelties of the season.

W. B. WOODRUFF, Westfield, Union Co., N. J.—In his catalogue of flower, bedding, and vegetable plants, has some useful talk about plants of various kinds.

WOOLSON & CO., Passaic, N. J., make a specialty of Hardy Herbaceous and Alpine Plants. Their catalogue adds to last year's list, those plants which have been tested, and the new ones that are now offered.

NURSERYMEN.

JAMES DONALDSON, executor of John Donaldson, will continue the business of the Kittanning Nurseries at Kittanning, Pa., with floriculture stock in addition.

ROBERT DOUGLAS & SONS, Waukegan, Ill., make a specialty of evergreen and ornamental tree seedlings, which they raise by the million.

FERRIS, MINARD & CO., Poughkeepsie, N. Y., offer, besides a general stock of trees, a large list of small fruits.

C. A. GREEN, Clifton, Monroe Co., N. Y., makes favorable terms for small fruits of all kinds.

E. W. HARRINGTON, Palmyra, Wayne Co., N. Y., wholesale and retail lists and "Root Grafts for Beginners."

D. E. HOXIE, Northampton, Mass.—Catalogue of strawberries, grapes, and other small fruits, seed potatoes, etc.

C. W. KESLER, Bethany Church, Iredell Co., N. C., offers fruits of all kinds suited to the Southern States.

T. B. MINER, Linden, Union Co., N. J., sends a special list of seedling strawberries, his new grapes, etc.

E. MOODY & SONS, Lockport, N. Y. This, one of the oldest nurseries, offers "special rates by the car-load."

E. P. ROE, Cornwall-on-the-Hudson, Orange Co., N. Y., sends a chatty circular about new and old small fruits.

SHINN & CO., Niles, Alameda Co., Cal., a catalogue of trees, etc., suited to California, a large colored sheet, showing five varieties of the Japanese Persimmon.

C. M. SILVA & SON, Newcastle, Placer Co., Cal.—A general assortment of fruit and ornamental trees, adapted to California, including Japanese Persimmons.

B. F. TRANSOU & CO., Humboldt, Tenn., send their wholesale list, which includes a full assortment.

JOHN VAN LOON, New Amsterdam, La Crosse Co., Wis. With a general nursery stock, makes a specialty of small fruits, and offers them as premiums to those who subscribe to him for the *American Agriculturist*.

B. R. WESTCOTT, Richmond, Ind., is no new hand at the business, as he offers his 37th wholesale price list.

E. & J. C. WILLIAMS, Montclair, N. J., in their catalogue of small fruits in general, make a specialty of the "Duncan" strawberry and "Brighton" grape.

J. C. WOOD & BROTHER, Fishkill, N. Y., send a full and illustrated catalogue of fruit and ornamental trees, shrubs, and give good advice as to planting.

T. C. YEOMANS & SONS, Walworth, Wayne Co., N. Y., send a general catalogue, and give useful instruction in planting and pruning, with illustrations.

FOREIGN.

JOHN A. BRUCE & CO., Hamilton, Canada, are no novices, for we have their 27th annual catalogue, and a very creditable one it is. Yankee notions not excluded.

WILLIAM RENNIE, Toronto, Canada.—Its neat exterior of Scotch plaid, is borne out by the contents. Our Canadian neighbors are well served by their seedsman.

WILLIAM THOMPSON, Tavern St., Ipswich, England, is known to botanists as one of the few seedsman, not only in England, but everywhere, as being, while "in the trade," an accurate botanist. His supplementary catalogue for 1878, contains many rare American seeds.

FARM IMPLEMENTS, MACHINERY, FERTILIZERS.

BELCHER & TAYLOR AGRICULTURAL TOOL CO., Chicopee Falls, Mass., offer a great variety of farm implements, and among them excellent feed cutters, plows, cultivators, and notably a hand-power threshing machine.

WM. L. BOYER & BRO., 2101 Germantown Ave., Philadelphia, Pa., describe their Union Railway Horse Power and Farm Grist Mill in a special circular.

CHICAGO SCRAPER & DITCHER CO., No. 34 Metropolitan Block, Chicago, Ill. The use of their Scraper and Ditcher is illustrated with great fullness, and their recently introduced "Screw Harrow" presents a novelty in the way of implements, of which we hope soon to know more.

THE FARMER'S FRIEND MANUFACTURING CO., Dayton, Ohio, make the Farmer's Friend Grain Drill, which received the Centennial Grand Prize Medal and Diploma. The feeding apparatus of this drill is its prominent feature. It sows all sorts of seeds, with fertilizers if desired.

A. B. FARQUHAR, York, Penn., issue a handsome illustrated catalogue of their wares, which include everything for use on the farm in the way of tools, etc. The

specialties are steam threshers and separators, the Farmer's Favorite Grain Drill, and harvesting machines.

FRICK & CO., Waynesboro, Pa., describe their Eclipse Steam Engine, which they offer in both portable and stationary, and combined portable and stationary shapes. They also make a grain separator, cleaner, and bagger.

A. W. GRAY & SONS, Middletown Springs, Vt., illustrate the merits of their one, two, and three Horse Powers, with their various machines for sawing wood.

THE MAPES FORMULA & PERUVIAN GUANO CO., No. 158 Front St., N. Y., are making a literature of their own. Their recent circulars give a great amount of information, and will be of interest to all who use fertilizers.

G. WESTINGHOUSE & CO., Schenectady, N. Y., give full particulars of their Separators and Threshers, with the horse and steam powers for driving them.

MISCELLANEOUS.

AMERICAN DRIER CO., Chambersburg, Pa.—A simple apparatus for drying fruits, vegetables, etc.

BAUSCH & LOMB OPTICAL COMPANY, No. 37 Maiden Lane, N. Y., and Rochester, N. Y., who have supplied the *American Agriculturist* with more microscopes than were ever before made for one order, send a catalogue of Compound Microscopes and other optical instruments.

J. S. BIRCH & CO., No. 38 Dey St., N. Y.—Self-adjusting Watch Keys, Alarm Clocks, and other useful things.

CHADBORN COLDWELL MANUFACTURING CO., Newburgh, N. Y., make the widely known "Excelsior Lawn Mowers." They have done two good things, reduced the prices and diminished the weight of their mowers, which now go to Europe at the rate of over 1,000 yearly.

CLEVELAND NON-EXPLOSIVE LAMP CO., No. 42 Barclay St., New York, and Cleveland, O., send an illustrated catalogue. Their Library Lamp was noticed last month.

EVERETT & SMALL, No. 43 South Market St., Boston, Mass., are the sole makers of the "Matthew's Seed Drill," which they claim to be "the most perfect drill in use."

A. H. HEWES & CO., Cambridge, Mass., make illustrated flower pots, vases, & horticultural earthenware generally.

LAMB KNITTING MACHINE CO., Chicopee Falls, Mass., set forth the merits of the "Tuttle" Family Knitter.

T. H. McALLISTER, No. 49 Nassau St., New York, besides his general optical catalogue, issues one especially devoted to telescopes, spyglasses, and their uses.

MASSACHUSETTS ARMS CO., Chicopee Falls, Mass.—"The Maynard Rifle," and everything thereto appertaining.

E. RUHLMAN, Lockport, N. Y., claims that his "Hand-Cultivator, or Wheel-Hoe," is the best in use.

J. C. STRIBLING, Pendleton, R. I., makes the "Dixie Fruit Picker."

TREVOR & CO., Lockport, N. Y., make wooden labels of every size.

WILSON & HOWELL, Whippany, N. J., make Moore's Patent Duster for distributing Paris Green. It looks efficient, and we shall try it when there are any "bugs."

Bee Notes for March.

BY L. C. ROOT, MOHAWK, N. Y.

Let bees, out of doors, be left undisturbed, unless necessary to examine occasionally to see that the entrance does not become stopped by snow, ice, or dead bees. This sometimes takes place after a cold spell of weather, when the frost on the inside of the hive, accumulated from the breath of the bees, melts, runs down to the bottom, and there freezes. Those wintering in-doors should be left as entirely undisturbed as possible.

Bees and Grapes.

Mr. Jos. Lesley, of Montgomery Co., Pa., writes, "can you put me in the way of finding out what are the odors that are disliked by bees. I have fine grapes, and desire to eat them, but my neighbor's bees are always before me, so that I get about 20 per cent only of the yield."—If beekeepers are conscientious and honest persons, this is a question of even more importance to them than to those who cultivate grapes. It is a topic which has long been discussed. That many kinds of grapes will, from different causes, become cracked or broken, while yet hanging on the vines, is well known to grape growers. When the skin, from any cause, becomes broken, it is undeniable that, if honey be scarce, bees will suck out the juices. But the inference from the above inquiry is, that the bees attack and destroy sound grapes.

That wasps and hornets are capable of puncturing the skin of the grape, is evident to any one who has ever seen a magnified illustration of the serrated jaws of these insects, while the jaws of the honey-bee, under the microscope, appear entirely different; they are smooth and apparently pliable. This fact must convince any one that it is a physical impossibility for a bee to bite the skin of any fruit. I could cite various authorities to prove this, some of whom were equally interested in both bees and grapes. I have myself tested the matter repeatedly, watching the bees day after day, when honey was not gathered from the usual sources, and have never known an instance where the bees injured a grape, when the skin was not first broken from some other cause. The year 1869 was the poorest season for honey ever known, not a pound of fall honey being gathered by many swarms. We had over 100 swarms of bees at our home apiary, and at the same place about one ton of grapes. If, from any cause, a grape, or any kind of fruit, became broken, the bees would at once appropriate it. Had it been possible for them to puncture the skin, they

would have destroyed the entire crop, Yet it was impossible to find them injuring sound fruit. The late Mr. Quinby was for years largely interested in both bees and grapes, and his experience corroborated this conclusion. That it may be an annoyance to grape growers to have their vineyards visited by our bees, only for the purposes admitted, I am well aware, and I would be very glad if I were able to offer any suggestion for mitigating the trouble. I can conceive of nothing that would be powerful enough to keep the bees away that would not be detrimental to the fruit. Intelligent horticulturists agree that the honey-bee is exceedingly useful, if not indispensable to plants, by the aid it renders in the fertilization of many flowers. It would be difficult to imagine what would be the consequence if bees should become extinct. It seems not too much to claim that the benefit they are in fertilizing flowers, more than counterbalance the occasional depredations of which we complain.

Weight of Swarms.

The amount of honey consumed by the four swarms of bees reported last month, during Jan., was as follows: No. 1, 1 1/4 lbs.; No. 2, 1 lb.; No. 3, 3/4 lbs. These were indoors. No. 4, which was out of doors, consumed 6 1/2 lbs.

A New Potato—Burbank's Seedling.

Mr. J. J. H. Gregory, of Marlhead, Mass., is not so exclusively devoted to the introduction of excellent squashes that he neglects "wisdom's old potato," for he has made known several varieties of what people call, when they wish to write prettily, that "esculent tuber." Mr. Gregory's latest introduction among potatoes is unfortunately named "Burbank's Seedling," which he knows, as well as we, will, should it attain the popularity he hopes for it, be known as the "Burbank," and nothing else. That remarkable potato, the "Early Rose," the introduction of which (even at \$5 the lb.) was one of the great events of the present century, not only in itself resuscitated potato culture, but it has been the parent of a numerous and useful progeny, among the latest of which comes the "Burbank," and asks for a place

transplanted the same, and found that he got good potatoes, and good sized ones, at the end of the first season; and if a seedling was not satisfactory then and at once, it probably never would be so. Mr. Burbank's experience sustained Mr. Breese's views, for the first year, from the seed-hall, the yield was 3 lbs. 3 ozs., of good sized potatoes. Mr. Gregory presents us testimony of large succeeding yields, and though we have not yet tried the "Burbank," we have such confidence in his judgment that we shall plant it, expecting large returns. If any one expects that the "Burbank," or any other variety, will give him large returns from starved land, he should not grow potatoes for a living.

Science Applied to Farming.—XXXIX.

More Scientific Experimenting by Farmers.—Practical Conclusions.—Plans for Experiments Next Season.

In one of the experiments with corn, described in the last article, on three plots where potash was not supplied, the crop failed, while on three other plots, in which it was added in different combinations, the yield was good, and was as large with the potash in the form of German potash salts alone, as where nitrogen and phosphoric acid were supplied with it. In another experiment, where sixteen plots were tested with as many different fertilizers, wherever phosphoric acid was omitted the crop failed, and wherever it was supplied the growth was good. The yield of corn rose and fell with the amount of phosphoric acid, and paid no apparent regard to the other materials. The inference then is, that in the first case, potash, and in the other, phosphoric acid, was the article of plant-food most needed.

Mr. Sage's experiment, the results of which are given in the table below, tells a still different story, and a very instructive one. The most striking feature is that the crop was a total failure in

every case except the two where complete fertilizers were used. Dried blood, superphosphate, potash salts, and plaster alone, each brought crops no larger, and, if anything, poorer in quality than where no fertilizer was applied. The mixture of dried blood and superphosphate, corresponding to a first class "ammoniated" superphosphate, did scarcely any better. In each case the crop was as

Mr. Sage says, "all refuse corn and hardly worth saving." But with the complete fertilizers, the yields were good. Hen manure, which furnished all the ingredients of plant food, brought about 40 bushels of shelled corn per acre. The mixture of dried blood, superphosphate, and potash salt, which cost at the rate of \$6.40 per acre, and furnished nitrogen, phosphoric acid, and potash, in probably larger quantities than the hen manure, brought 60 bushels of very fine shelled corn to the acre. "This," Mr. Sage says "was such a crop as I like to have. It grew well all summer, and the corn was very fine. The

stalks were large and green when the corn was ripe, and will make excellent fodder."

I am very sorry there is not space here to give accounts of a number of other experiments, whose results are extremely interesting and instructive. One, in particular, from Mr. Lufkin, of the "Maine State College of Agriculture and the Mechanic Arts," and one of the very best I have received, by the way, is full of instruction. Three crops, potatoes, beans, and rutabagas, were grown. To yield these crops, the soil evidently needed phosphoric acid most, and nitrogen next. Potash seemed to do scarcely any good. According to Mr. Lufkin's figures, the gain from the use of nitrogenous superphosphates on potatoes and rutabagas was from \$50 to \$80 per acre. With the other articles there was either a much smaller gain or a loss, which, in some cases, was very considerable. With beans there was a loss in every case except the one with superphosphate alone, which brought a small gain. This accords with what Mr. Lawes, of England, says, as the result of 30 years' experimenting with fertilizers, that "it is not advisable to sow artificial manures with beans, peas, tares, or other leguminous plants. Corn [i. e., grain] and root crops will take all the artificial manure which the farmer can afford to pay for."

One of the most sensible and prominent farmers in our State, in referring to his experiment last season, says something very much to the point: "After footing up the gains and losses on the different plots, it occurred to me to strike the balance of the experiment as a whole. Some of the fertilizers brought a large gain, others a heavy loss. Taking the whole together, the value of the increased yield was more than the cost, but the balance on the credit side was small. Now I think this is a fair epitome of the success a good many of us farmers have with commercial fertilizers. We know we must put more manure on our farms than they produce. We have got to do that, or go under. We use the fertilizers we find in the markets at random, without understanding how or why. Sometimes we gain, sometimes we lose. If we know what ones to buy, and when and where and how to use them, we may, harring the weather—which of course we can not control—he fairly sure of a good profit every time. I am persuaded that the way, and the only way, to learn what are the wants of our crops and soils, and the best means to meet them, is by studying them with such experiments as these. Mine has cost me a little trouble, and has given me a good deal of pleasure in return. I feel that I have learned what one of my fields, in its present condition, stands most in need of, and have made up my mind what to give it next season. Meanwhile, I propose to go on with this experimenting, and see how much more I can learn about my farm and crops."

In the next article I shall have something more to say about these experiments, and give plans and directions for making similar ones the coming season. Meanwhile I am very glad to say that the proprietors of the *American Agriculturist* have become so impressed with the usefulness of these experiments for farmers that, with their wonted public spirit, they have undertaken to do for their large circle of readers, what the Experiment Station did for a limited number of persons last year, to wit, supply the materials of attested quality, and with full explanations and directions for use. So, I presume, the number will be very considerable, and the results valuable.

W. O. ATWATER.

Wesleyan University, Middletown, Conn.

BURBANK'S SEEDLING POTATO.

by the side of our now many valuable kinds. The form of the "Burbank" is shown in the engraving; it is of medium size, running remarkably uniform in this respect; medium as to season, excellent as to quality, whether boiled or baked, but its most prominent character is its abundant yield. Not long ago, it used to be thought that a potato from the seed must be cultivated for four or five years before its full size was reached, and its qualities known. But the excellent Mr. Breese, of "Early Rose" fame, changed all this. He sowed the seed from the seed-ball as he would tomato-seed; and

EXPERIMENT WITH CORN, BY CHESTER SAGE, MIDDLETOWN, CONN.

Soil: Heavy loam, very poor, hard pan subsoil. Previous treatment: 1874 manured with blood guano [slaughterhouse refuse], 300 lbs. per acre; crop, oats, 15 bushels per acre; 1875, no manure, hay, 3/4 ton; 1876, no manure, hay, 1/2 ton. Size of each plot, one row (79 hills, 3 ft. 9 in. apart), 18 rods long, making about 4 square rods area. Amounts of fertilizers: 800 lbs. per acre, except hen manure handful to each hill. Fertilizers applied in the hill, mixed well with the soil and covered with earth before dropping the corn. Plowed May 9. Planted May 16. Cultivated both ways and hoed three times. Harvested Oct. 15. Yield: Corn in the ear, measured in a bushel basket, as below.

No.	Fertilizer.	Valuable Ingredients.	APPEARANCE OF CROP.			YIELD, CORN IN EAR.	
			Stalks.	Ears.	Kernels.	Per Plot.	Per Acre.
1	Dried Blood I.	Nitrogen. Phosphoric Acid. Potash.	Poor, 3 ft. high.	Small, not filled.	Small, imperfect, dull color, bitter taste, mouldy.	1/2 bushel.	20 bushels.
2	Superphosphate II.		Small, poor.	Small, better filled.	As 1, except less bitter and not mouldy.	1 bushel.	40 bushels.
3	Potash Salt III.	Potash.	Small, poor.	Same as 1.	As 1, but not mouldy.	3/8 bushel.	20 bushels.
4	Mixture I+II.		Small, poor.	Same as 1.	As 1, but not mouldy.	3/8 bushel.	20 bushels.
5	Mixture I+II+III.	Plaster.	Large, fine, green.	Large, long, well filled.	Large, bright, sound, sweet, very fine.	3 bushels.	120 bushels.
6	Plaster.		Small, 2 ft. high.	Small, not filled.	Poorer than 1.	1 bushel.	40 bushels.
7	Nothing.	Hen Manure.		Very poor, but better than 1, 2, 3, and 4.		1/2 bushel.	20 bushels.
8	Hen Manure.					2 bushels.	80 bushels.

Very good, but stalks smaller, ears shorter, kernels smaller, and yield less than 5.

A Cottage, Costing \$250.

BY S. B. REED, ARCHITECT, CORONA, LONG ISLAND, N. Y.

This plan was designed for a simple cottage, with sufficient accommodations for beginners in house-keeping with limited means. It is arranged as the Wing of a larger house to be erected in the future, as indicated in the dotted sketch adjoining ground plan. (The building, with the proposed enlargements complete, will be given in a subsequent number of the *American Agriculturist*.) To a certain extent one's dwelling is an index of his character. Any effort at building expresses the owner's ability, taste, and purpose. Every industrious man, starting in life, has a right, and should be encouraged, to anticipate prosperity, as the sure reward of honest worth; and he may, with propriety, give emphasis to such anticipations in every step, and with every blow struck. His dwelling may well express the progressive character, rather than a conclusive result. Beginning a home by starting with a room or two, as present means will allow, and increasing its dimensions as can be afforded, without the precarious aid of the money-lender, is honest, independent, and best provides against the ever-changing vicissitudes of life. The first step towards building consists in the preparation of plans. These should be sufficiently comprehensive to embrace all probable requirements. If only a small beginning is intended, it should be made to exhibit some degree of completeness, and be arranged to conform with the proposed future enlargements without serious alterations....

Exterior, (fig. 1).—In view of the relation this structure is to bear to a proposed main house, and to allow for the grading likely to be required in the ultimate completion of the whole, the foundation is made to show four feet above the ground. Such elevation adds to the prominence and good appearance of the building, and relieves the interior from the dampness likely to result from a closer contact with the soil. The style is simple, neat, and favorable for the using of ordinary materials and methods of construction.

....

Fig. 2.—INTERIOR OF COTTAGE.

Construction.—For economy, and in prospect of a future enlargement that shall include ample cellars, such excavations are omitted for this building.

The Foundations are brick piers, extending below the reach of frost, and 4 feet above, and the spaces between them are close-boarded with sheathing, making an inclosure useful for many purposes. If desired, a sort of temporary cellar may be made, by deepening the central portion of this inclosure a foot or two, and banking the loose earth against

Fig. 1.—EXTERIOR OF COTTAGE.

the inside of the boarding. The Framework and other parts are substantially constructed, of materials as indicated in the appended estimate. The Chimney rests on the central pier of the foundation, (which is strengthened by the central pier of the foundation), and has two flues, with metal thimbles in the bottom of each—one to receive the stove-pipe from the Living-Room, and the other to serve as a ventilator for the Bed-room. All of the materials are intended to be of merchantable quality. The siding, flooring, and casings, are mill dressed. The sizes of the sash are 2 ft. 8 in. by 5 ft. 2 in., and of the doors, 2 ft. 8 in. by 6 ft. 8 in., all 1 1/4 in. thick, and may be found ready-made, and seasoned, in the stock of any regular dealer.... In the following estimate, the item of \$20, for carpenter's labor, may seem very little. This amount is allowed for preparing the building ready for the plasterer, and is entered in this manner for convenience in making the calculations. Adding to the above amount the cost of such labor in the "completed" parts, will make a total of \$50.

Estimate, cost of materials and labor:

1000 bricks, laid, at \$12 per M.	\$12.00
124 yards plastering, at 20 cents per yard.	24.80
630 feet of timber, at \$15 per M.	9.50
2 sills, 4x6 in. 18 feet long.	1 girder, 4x6 in. 18 feet long.
2 sills, 4x6 in. 16 feet long.	9 beams, 3x6 in. 16 feet long.
4 posts, 4x6 in. 10 ft. long.	14 ceiling bds., 2x4 in. 16 ft.
75 wall strips, 2x4x13, at 11c. each.	8.25
98 siding, 9 1/2 inches, at 25c. each.	24.50
Cornice materials	5.00
50 shingling lath, at 5c. each.	2.50
12 bunches shingles, at \$1.25 per bunch.	15.00
36 flooring, 9 1/4 in., at 25c.	9.00
7 windows, (complete), at \$6.	42.00
4 doors, (complete), at \$5.	20.00
2 stoops and closets, (complete)	20.00
Nails, \$4; painting, \$14; carting, \$5.	23.00
Carpenter's labor, (not included above)	20.00
Incidentals	12.25
Total Cost.	\$250.00

A Machine for Planting Potatoes.

We have heretofore referred to a potato-planter, which cuts the seed, opens a furrow, drops the sets, scatters any dry fertilizer in the furrow, and covers seed and fertilizer—all at one operation. This machine is True's Potato Planter, which we here illustrate by engravings. It is no new invention, but has been in use by a large number of extensive potato growers for some years. It was exhibited at the Centennial, where it attracted the notice of the English Judge of agricultural machinery, who procured several machines for himself and his friends. The value of a really effective machine, which will plant six acres of potatoes in one day, doing the whole work completely, and as well as, if not better than, it can be done by hand, is obvious. That this machine is thus effective, we are well assured, and though we have not yet tried it in the field,

Fig. 2.—BOTTOM OF HOPPER.

we propose to do so the coming season. The general view of the machine is given at figure 1. It consists of a two-wheeled frame, upon which is a hopper for the seed potatoes, another hopper in front of this is for the fertilizer; a plow, through the standard of which the cut sets drop into the furrow, which it opens, and a pair of scrapers in the rear, by which the furrow is closed, and the sets are covered. In the bottom of the hopper are a series of revolving holes, into which the potatoes drop, and as they are carried around upon a stationary floor, they are thrust against a blade, which slices off a piece sufficiently large for a set. This arrangement is shown at figure 2. The operation is certain and even, and the only thing which can interfere with it, is the presence of a potato too large to drop into the holes. This is provided against by taking care to break any large potato, or to remove

Fig. 1.—TRUE'S POTATO PLANTER.

any very large ones. Different sets of holes are furnished, to be used with potatoes of various sizes, from very small ones, up to those of average bulk. The machine is drawn by one horse, and the wheel-mark is intended to be a guide for planting each succeeding row. It is made under the supervision of the inventor, Mr. J. L. True, by Messrs. Nash & Brother, of 7 College Place, New York.

THE NORTH-WESTERN DAIRYMEN'S ASSOCIATION met at Chicago, Dec. 11, and following days. Various papers on interesting subjects were read, such as "Chemical fertilizers, their uses and application"; "Barn-yard manure, its value, and how applied"; "The best varieties of grasses for hay and pasture," and similar topics. Dr. Jos. Tefft, of Elgin, Ill., was elected President, and William Patten, of DeKalb Co., Ill., Secretary.

The Hare-Indian Dog.—(*Canis familiaris*.)

The dog represented upon this page will be readily recognized as a relative of the so-called Esquimaux dog. The similarity in form and feature between the dogs inhabiting the arctic countries, and which are classed under the general term Esquimaux, and the wolf of that northern region, is so close that naturalists consider the dog to be descended from the wolf. It is known that the dogs have bred with the wolves, and the half-bred animals have been tamed and domesticated. In general, the dogs of the different varieties known as Esquimaux, have gained little or nothing over their wild ancestors by their entrance into domestication and servitude. Starved, for the greater portion of the year, and kept so hungry that they occasionally attack and consume each other, they are at other times but barely half fed that they may work in the hardest manner in drawing the sledges of their savage masters. They are at the same time so cruelly used and beaten, when forced by the pangs of hunger, they neglect their work to help themselves by stealth to the scanty provisions laid up for the use of their owners, that they evince none of the kindness of disposition or affection for their keepers shown by dogs of other races; but on occasions when made furious by severe torture, they turn upon their tormentors, and unless driven off, would soon rend them to pieces, and devour them.

The dogs of the Hare Indians, while they closely resemble their wilder relatives in some respects, are rendered less savage by better treatment and relief from degrading labor. These Indians inhabit the region around the Great Bear Lake and the Mackenzie River in North America; and while the Esquimaux dog is found throughout the whole of the Arctic Zone, this variety inhabits only the American portion of it, and is confined to the possession of the Indians mentioned, and one or two other neighboring tribes. The dog has a mild countenance; a small head; slender muzzle; erect stout ears; the oblique eyes of the wilder races; slender legs; a broad hairy foot, and a hushy tail which it generally carries curled over its right hip, as is done by the true Esquimaux. Its fur is long, especially upon the shoulders; and beneath it, all over the body, and even upon the tail, there is a coat of thick wool. The hair upon the top of the head is long, and upon the cheek is not only long but turns backwards, giving the appearance of a

ruff or collar around the throat. The face, muzzle, belly, and legs, are white, and a white line passes over the crown of the head. The ears are white in front, and fawn-color behind. The end of the nose, eye-lashes, roof of the mouth, and parts of the gums, are black. The back and sides are grey, or

DOG OF THE HARE INDIANS.

lead-color, mixed with fawn and white, not in patches, but shaded into each other; the hushy tail is white beneath and at the tip. The feet are covered with long hair, which conceals the claws. The soles are partially covered with hair, but there are naked protuberant callosities even in the winter time upon the soles, as there are in all the northern species of dogs and wolves. The ears are somewhat nearer to each other than in the true Esquimaux dogs. This race is used only for hunting,

The Blue Arctic Fox.—(*Vulpes Lagopus*.)

One of the most valuable of the different species of foxes, considering the fur as the measure of the value, is the Arctic fox.

This animal is eagerly hunted all through the Arctic regions, and is in great repute on account of its beautifully silky fur. This is perfectly white in the winter, at which season it has the greatest value in the hunter's estimation; at other times it becomes of a bluish leaden-grey color, whence the animal takes one of its names. It is called the White Fox, the Blue Fox, and the Stone Fox. When the fur has a peculiar bluish-grey tint, it is valued nearly as highly as when white, so that it is hunted at all seasons, excepting at the time when the coat is changing. It inhabits both the Asiatic and American Arctic countries, but the largest numbers of skins are procured in America by the hunters of the Hudson Bay Company, at whose annual sales, in London, the fur brings very high prices, sometimes surpassing a hundred dollars for a single skin. It is rarely that more than a hundred skins are sold at one of these sales, and frequently the number is much less than that. As is peculiar to some kinds of foxes, the soles of the feet of this species are thickly covered with hair, from which it gets the name *Lagopus*, or "hairy-footed." It subsists upon birds, and exhibits great cunning in the capture of its prey. It possesses the power of imitating the cries of

birds, and by this deceit is enabled to entice them to destruction. While it is thus remarkably acute in providing itself with food, yet it has not the suspicious wariness which renders other species of foxes so difficult of capture, and so successful in eluding danger and baffling pursuit. It is easily enticed into traps, and will generally permit a hunter to approach within easy range of a shot-gun. It is not that it is so sparsely scattered over its barren hunting grounds, and that its food were not equally sparsely supplied, it would become so easy a prey, that it would be in danger of early extermination. It lives in burrows which it excavates in the ground during the summer months, and is sociable in its habits,

THE BLUE ARCTIC FOX.

and as may be reasonably supposed, their occupation tends to develop finer and higher instincts, greater courage, and altogether a better and gentler disposition towards their owners, than exists in the wholly brutal and savage Esquimaux dog, made so, no doubt, by cruel treatment and hard labor.

the burrows being formed in groups of twenty or thirty in one locality. When alarmed at the approach of a human being, or other enemy, it retires to its burrow, but from curiosity or for some other reason, it continually protrudes its head and yelps at its disturber, so that its retreat

is of little avail in securing its safety. The Blue Arctic Fox is smaller than our common Red Fox, it rarely surpassing eight pounds in weight, and being no more than three feet in total length. It possesses a very bright and intelligent eye, of a hazel color, and its features generally are devoid of that sly cunning which characterizes the fox with which we are all so well acquainted, and from which we take such pains to guard our poultry houses.

Among the Farmers.—No. 26.

BY ONE OF THEM.

Horse Experience.

The friend who sent to my pasture the Arabian mare which he picked up at an auction sale in New York for a song, bought a mare with foal at foot last spring. Pretty soon he found that the mare was probably hopelessly lame, and the foal looked like a cripple, though lively enough, and not lame. One hind fetlock joint was much bent, so that it traveled on the outside of the hoof only. It was a severe tax upon the mare to make the journey of 18 miles to my farm, even after a rest of a week at a good stable. When there, the wisacres were all at a loss to know what and where the difficulty was. Some said it was a dislocation of the shoulder from a fall; others, an inflammation of the shoulder joint; others, that it was in the foot. The fact was, she bore no weight upon the off fore-foot, hardly allowing it to rest its own weight upon the ground. Of course the shoulder was all drawn up, and looked swollen. The hoof did not feel hot—at least, not very hot. She was a big coarse creature, awkward, and ungainly, but feeding well and giving a plenty of milk. The foal was large and thrifty, and its crooked leg was rapidly getting straighter. It was some time before we found out that the ailment from which the mare suffered was

Navicular Disease.

This it clearly was, for when, after a while, she began to bear any weight upon the foot, she "pointed,"—that is, she touched her toe only to the ground. She gradually improved, so that she walked, but stumbled greatly, and limped badly when forced to trot. Her shoes were pulled off, and she was left to wander in wood pastures, and pretty much where she liked, for she was not worth stealing. She was bred to a good large horse—handsome and stylish, with fine action, great spirit, and a natural fast trotter. He is just her opposite in every respect, except having a good road gait, and good size. After two months' rest we were rather surprised to find that her lameness had nearly gone. It now recurs occasionally and slightly. She is a very serviceable animal, and will take a family "Rock-away," with four people in it, up hill and down for hours, at a gait of ten miles an hour, with little show of fatigue, "going for" every hill as if it were a pleasure to trot up it. The diseased foot is smaller than the other; that is always the case with *navicularis*. It is now growing wider at the heel, however, and the evidence of former fever, in the constricted band which shows as a deep depression all around the hoof, is at once evidence that the diagnosis was correct, and that health is measurably restored. After it became evident that she would be able to do farm work, I proposed to my friend to keep and use her a year for her next foal. To this he consented, and it has opened my eyes to

The Pleasure of Driving a Big Horse.

"Mollie McGuire," as we call her, is 16½ hands high, I suppose; perfectly willing to pull, and so powerful that no ordinary load taxes her strength. She is a fair roadster, too; perfectly docile and easy to drive, but inclined to stumble. Once she turned a summerset in the shafts. She "brought up" on her back, with all her feet and her head under the forward axle, unable to breathe, and yet refraining from struggling, as if falling down in the shafts had been the daily experience of her life. I suppose it took about one minute, but it seemed an hour, before we could run the wagon back, unbuckle reins and the throat-latch, and give the poor thing a chance to draw her breath, and get up. This is a

digression. Heretofore I have always driven rather small horses—say those weighing 900 to 1,050 lbs. "Mollie" weighs 1,300 to 1,300, and is all bone and muscle. I would not have believed it possible that so great a difference in the ease of motion would be perceptible to one in the wagon, when drawn at just the same speed. "Mollie" swings along as easily as if she had force in reserve for ten times the labor; while our 900 lbs. Kanuck, who is as willing as possible, and will haul a ton of coal up from the station alone, if the roads are good, is just a little, but constantly, irregular in his gait according to the road, whether it is sandy or deep with mud, level or slightly undulating. It is a great satisfaction to feel as if your horse's strength and willingness could hardly be overtasked, and I am satisfied that for country use one good big horse is more useful than a pair of small ones; and on the road is quite as pleasant to drive.

Rest as a Cure-all for Horses.

Two years ago I had a mare go lame with a spavin. She was worked a good deal until about a year ago, since which time she has had profound rest, and meanwhile has given me an Orloff foal. She had been blistered and treated more or less, but grew worse. Now she does not go lame at all. "Mollie's" *navicularis* was certainly cured by rest, and I have repeatedly known old cripples turned into the woods to die, pick up and come out, if not sound, yet valuable for years afterwards. Nature is the best physician, almost every time, for the common ills of our domestic animals, and so far as horses are concerned, particularly as affecting ills of their locomotive system, we cooperate best with Nature when we give them rest. There are, however, cases when medicine, the knife, and the burning-iron are necessary, and must be speedily resorted to, or it will be too late. If we call a veterinarian, it is more likely than not that he will feel constrained to do something or give something in order to satisfy us, when, if he could do exactly what he thought was best, without reference to what he thinks our wishes may be, he would try the "let alone practice."

Weaning a Foal.

The books indicate that it is an easy matter to wean a foal, and very little is said about it. One of my mares had an abundance of milk, the other was not properly treated before foaling, and to that I attribute the fact that she gave a small quantity. She foaled after having been only a week or ten days at pasture, and both she and the colt suffered, as I suppose, from the relaxing effect of the change of diet, which occurred just when she most needed her strength and vigor. When the foal of the other mare was seven months old, we weaned it, and learned two or three interesting facts. One is, that it would not have been difficult to take one foal away and give the mare another, for she allowed the one not her own to suck repeatedly, her own being absent. I have frequently regretted not having put the little colt with the big mare at that time for a permanency. This mare gave what struck me as an enormous quantity of milk. The foal was removed at about 9 o'clock; by noon, her udder seeming much distended, it was milked out, and nearly two quarts of milk were obtained. It was not measured, so we may fairly say it amounted to three pints. In about three hours it was full again, and a similar quantity was drawn. This seemed to be all that the udder would contain, and about the time required to secrete it. At this rate the mare was giving twelve quarts of milk a day, and very likely more, for the almost constant draft which a foal makes is a constant stimulant to milk secretion. The European goat-milkers, who drive their little flocks from door to door, and milk them as they sell the milk, draining them of the last drop many times in a day, get a great deal more milk than if the goats were milked but twice a day. We found that the mare above alluded to would get along without being milked, except when she was wanted for work, when it was of course best and most humane to empty her udder. It, however, was next to impossible to keep her away from her foal, or the foal away from her, if both were free and within sound of each others calls. The mare would manage to break-down almost any fence, and the foal would

leap almost any fence on the farm, so one of them had to be stabled all the time for nearly two months.

Green Manure Crops.

Cheap and good manure is getting to be more and more important every year. We are finding it harder to buy manure, and more difficult to get concentrated fertilizers that are to be depended upon. Nevertheless, farmers make little use of green manure crops. It is hard to change old practices sufficiently to plow under a good crop of clover or even of buckwheat. I have a very poor opinion of buckwheat as green manure. Rye is much better, and one can plow that under early enough to sow something else, to be either harvested or plowed under as the case may be. For instance, I witnessed the following successful treatment of a rough, stony, poor, gravelly lot, and hope to be able to carry out something quite similar myself this year: An old neglected lot, five acres of which would hardly pasture a sheep, was plowed and sowed with rye, which wintered well. A good many stones were picked off, and about the first of June, when the rye was heading well, it was rolled down and plowed under. Stones were partially picked off again—that is, the larger ones were—and about the first of July buckwheat was put in. Of this a good crop was harvested, and the straw, with a little addition of some other light manure, was spread back, and rye was sowed again in the autumn. This gave another opportunity to pick off the stones, and the result was that when the rye was a second time plowed under, the quality of the soil was so good that corn was planted with fertilizer in the hill. Of this a very fair crop was secured, and other farm crops followed. Now if cow-peas could have been sowed at the last hoeing of the corn, they would doubtless have covered the ground well. Then they might have been plowed under just before frost—as soon as the corn could be cut up and removed; then wheat or rye might have been sowed.

Light, poor land, really needs a growing crop to cover the soil all the time. Rye offers several advantages over other crops. It occupies the soil from October to June—eight months—during which time, when the ground is not frozen, the roots are absorbing nutriment and growing, so that when the warmth of spring comes the plant makes most rapidly the astonishing growth with which we are all familiar. It is a very certain crop, not being liable to winter kill. Besides, it is cheap, the seed costing seldom over \$1.50 per acre.

Red Clover is no crop wherewith to manure poor land, though one of the best for land in good heart. It must, however, occupy the land fully a year, but after a good crop has been plowed under and the land limed, almost any crop may follow.

Feeding off before Plowing.

We raise few green crops which may not be fed off with sheep before they are plowed under. Turnips, rye, clover, and cow-peas may thus be treated, often most advantageously. The difficulty I find is that I do not and can not well keep sheep. Feeding off with other stock is not so satisfactory. The manure is less evenly distributed, and the crop is less consumed than trodden down. It is important to save labor, and the advantage of green manuring is that all that great amount of labor in harvesting, curing, storing, feeding out the crops, and finally carting out the manure and spreading it, is saved. The actual value of any crop as manure is never so great as when it is plowed under just at the right time. When it is fed, we gain perhaps in other ways, but we lose in manure. This loss must be made up by the use of leaves, mold, muck, swamp hay, or other articles really foreign to the farm, or at least foreign to the arable land of the farm.

In the vicinity of a large city, or of any locality where many horses are used, no branch of farming is more profitable than

Taking Horses to Board.

The price of board varies greatly, but it is never less than the value of the hay and grain actually consumed, estimated at the full market price. When one can get all the horses he can accommodate, and has room for a goodly number, his fortune as a farmer—a very moderate fortune—may be

said to be made. There is always considerable competition, for every one likes to have his yard well filled with good manure in the spring, and yet with few horses and cows, and a diligent use of absorbents, that is, of leaves from the woods, muck from the swamp, sods, and such things, the manure heap will increase just about as fast, with no more labor or responsibility. Of course with more "help" we might board horses and cart muck and leaves too, and so have our muck and manure heap grow in proportion to the number of horses and cattle stabled, but I notice that that is not the result generally seen. The stipulation in regard to boarding horses usually is that they shall have all the good hay they will eat, and towards spring a certain quantity of oats daily is ordered in addition. Boarding horses thus get in the way of nosing over a good deal of hay, which is wasted, for as they lose their relish for dry hay, they pick out the nicer sorts, and refuse the rest. Our own horses are fed more economically, when they have cut hay with bran and corn-and-oat feed, with only such dry hay as they will eat clean, and it would, I think, be better for both the farmer and for the horse owner, if the stipulation were that the horse should be kept in good flesh or gaining weight from November to May, leaving the farmer to feed hay, grain, or roots, as he could do most economically.

Talks on Farm Crops.—No. 13.

By the Author of "Walks and Talks on the Farm,"

"Harris on the Pig," etc.

Mr. Calvin Chamberlin, of Maine, writes: "I have been a reader of the *American Agriculturist* for several years. Your article in January is of special interest, as I have given much time and thought to the matter of forage plants, as substitutes for pasturage and hay. I am situated at a thriving village, and supply some of our neighbors with good milk. I moved from a 200-acre farm in 1852, to my present place, then 20 acres—nearly one-half of which was covered with the original forest. I started a nursery of apple-trees as a leading business; but at the end of a few years was glad to put the land to better use. I then got some Jersey stock, beginning with grade heifers and a thoroughbred bull. I have since owned two other full-blood bulls, and kept each of the three two years. I have raised and sold several very fine cows, and have usually four cows in milk. My original 20 acres has been changed by cutting off about one-half the wood-lot, leaving a belt on the north and west for a wind-break; and I have given four acres for the way of a railroad, and a site for a spool-factory.

"With my present available land,—not over ten acres, for all purposes of pasture, meadow, tillage, orchard, and garden,—and keeping a horse, and generally a bull, and raising heifers, and finding a good account in the Jersey cows, you can understand how it is that I am interested in a well-presented article on a forage-crop. I have usually brought home some hay from out-lying lands a few miles away; but for the main dependence, I make the best use I can of these ten acres. I have grown very heavy clover by using stable manure, wood ashes, and superphosphates. My last purchase of ashes was from the spool-factory—100 bbls., well packed, made from white birch, at 50 cts. per bbl. Alsike clover gives me as much weight of hay as does the largest red, and I think of more value. I have been through with all the usual experience with Hungarian Grass, Millet, and Western Corn, as fodder crops, and have settled on an *early sweet corn*. The cows and the horse have been consulted in their tastes while arriving at this result.

"I plant in rows about $\frac{3}{4}$ ft. distance, and hills $1\frac{1}{2}$ to 2 ft., with 5 to 8 stalks to the hill. Give flat tillage; hoe once or twice; use scarifier freely. The crop grown in this manner is as heavy as that grown in drills with more seed; and being more open to the sun, I imagine is more fully charged with the valuable elements. This mode of planting has the advantage of easier handling in the daily green rations; and the surplus of crop ma-

tures good ears, of which I usually have a few bbls. to be ground with the cobs, which goes well with the cows and calves in a mixture with cotton-seed meal. Besides the crop of potatoes, I grow some roots. Formerly I aimed to have 100 bushels of carrots to each cow wintered. I have now changed to mangel-wurzel and turnips."

"Mr. Chamberlin," said the Deacon, "seems to second your opinion that we are making a mistake in sowing the large varieties of Western and Southern corn for fodder, and that we ought rather to sow small-growing early kinds. I confess to have thought otherwise. Possibly, however, there is some truth in your idea."

"Depend upon it," said the Doctor, "it is one of the most important points in growing corn for fodder. The only objection that can be made to corn as a forage plant is that it is not nutritious enough. It is too bulky. I am not sure that you want an *early* variety. What is needed is a variety that produces small, fine, highly nutritious stalks, with an abundance of leaves. You do not want ears, but rich, soft, easily digested stalks, and it is not demonstrated that a variety of sweet corn is any better than a variety of other corn. Your stalks, last year, from a small early variety of common corn, were certainly sweet enough. Sugar is no more nutritious than starch, and as it ferments readily, there is great danger of its being lost from exposure to the rain in curing, or from fermentation."

"Mr. Chamberlain's method of planting," said I, "is a good one when the corn is to be cut up green for daily use in summer. But when it is sown on a large scale, to be cut with a reaper and tied into bundles to be cured for fodder in winter, I think my method of drilling it, thickly in rows, is better than planting it in hills. We have in this section a bean-planter that plants two rows at a time, 2 ft. 5 in. apart, and drops the seed in hills 12 or 15 inches apart in the rows. I have used this for fodder corn, dropping eight or ten kernels in a hill."

"And you had a grand crop," said the Deacon. "True," said I, "but no better than I have had since we drilled in a continuous row. The plan to adopt is the one which is the most convenient under the circumstances. The only thing that need be insisted on, is to sow it in rows wide enough apart to admit the free use of the horse-hoe or cultivator. Good crops are occasionally grown by drilling in the seed in rows seven inches apart, or by sowing broadcast, but they are the exception. A poor, sickly looking crop is the rule. For the best of 'Maize hay,' we want a small-growing variety, the richest and best land, and thorough culture."

But it is not an easy matter to convince a man that a "big crop" is not always the best. I was talking to-day with a farmer about barley. He was grumbling at the price. He raised the two-rowed kind, and could only get 56 cents per bushel. "You could have got 75 cents," said I, "for a choice sample of six-rowed barley."—"But you raise," he replied, "ten bushels more, per acre, of the two-rowed, than you can of the six-rowed."—"That may be sometimes the case," I replied, "but the crop which is the most easily raised is seldom the most profitable. You sow wheat after the barley, and it is reasonable to suppose that you would get better wheat after the smaller and earlier crop of six-rowed barley, than after the larger and late crop of two-rowed barley. It removes less plant-food from the soil. And at present prices, a crop of six-rowed would bring in more money than a crop of two-rowed. For instance, you have 50 bu. of two-rowed barley, per acre, and sell it for 56 cents per bushel, or \$28 per acre. If you had 40 bushels of six-rowed, and sell it at 75 cents, you would get \$30 per acre, and the cost of threshing, cleaning, and drawing to market is less on the 40 bushel crop of six-rowed, than on the 50 bushel crop of two-rowed. You get more money per acre, and the crop impoverishes the land less."

"You admit, then," he said, "that you can grow a larger crop of two-rowed than six-rowed."

"No, I do not. But it doubtless requires," said I, "richer land to produce a maximum crop of six-rowed than a maximum crop of two-rowed—just as it requires richer land to produce a maximum crop of early Kent peas, than a maximum crop of Mar-

rowfats. The early, short-strawed, six-rowed barley, requires richer and better land than the later and longer strawed two-rowed kind. To grow choice, heavy six-rowed barley, you require well-drained, rich, clean, mellow land, and these requisites being provided, there is no crop which, in proportion to the labor, and taking one year with another, affords a better profit."

"Farmers will not sow much barley this year," said the Deacon, "spring wheat and oats pay better at present prices."

"If so," said I, "those farmers who have good land, well adapted to the crop, had better stick to barley. A short crop means a good price and larger profits. But the main thing is to make the land rich, warm, and mellow, and to sow early. We are getting commercial manures at comparatively reasonable rates, and they will pay as well on barley as on any other ordinary farm crop. If we cannot afford to use them on the whole field, there are usually some light, sandy knolls, or poor spots in the field, where a little artificial manure would make all the difference between a good crop and a bad one. There are sandy knolls on my farm that will not produce 8 bushels of barley per acre without manure, but when a dressing of manure is given, will give a crop of 48 bushels per acre. And you must recollect that I am *obliged* to spend precisely as much labor and money in plowing, harrowing, rolling, sowing, cutting, and raking these poor portions, as those producing a good crop."

"On these poor sandy knolls," said the Doctor, "I should have more faith in some well-rotted barn-yard manure, than in artificials."

"Perhaps so," said I, "and in fact we are to-day drawing out some 'scrapings' from the barn-yard, and spreading them on the poorer, sandy portions of the field where we intend sowing barley. I have done this for several years with great advantage. But if you can not do this, then try some artificial manure. I should prefer equal parts nitrate of soda and superphosphate, unless I could find some manure that would afford soluble phosphoric acid and available nitrogen at less cost."

"If you have a good sod to plow under for corn," said the Deacon, "and after the corn is harvested can plow the land in the fall, the decayed sod will be brought to the surface, and if the land is not too heavy, you can sow the barley in the spring without again plowing. The sod will be where the roots of the barley can get hold of it, and it will be equal to a good dressing of manure. And besides this, the sods keep the ground loose and mellow, which is what is wanted for success in growing barley."

"A little artificial manure," said the Doctor, "sown in the spring, and mixed with this decaying sod, will be a great help. The nitrogen and phosphoric acid of the fertilizer will make this sod equal to the richest and best manure. It is good in itself, but you will not get the full benefit from it without a little addition of nitrogen and phosphoric acid."

"The Doctor is right," said I, "and the only question is, whether we can buy the nitrogen and phosphoric acid cheap enough. As a rule, we can make manure cheaper, by feeding more grain, bran, oil cake, etc., to stock, than we can buy it. But it will be found that those who make the most manure will be the largest purchasers of artificial fertilizers. It is almost impossible to get as much manure as we can use to good advantage."

"You can not raise good barley," said the Doctor, "unless your land is thoroughly underdrained."

"Unless it is naturally drained," said I. "And even then it is not drained as thoroughly as we wish. Something may be done in the way of letting off surface water that will greatly facilitate spring work. On my farm we can often let off thousands of gallons of water while the ground is partially frozen in the spring, and before the water has time to soak into the soil. If it soaks into the soil, it has to stay there until it evaporates into the atmosphere. And every gallon we let off, gives the sun and air a better chance to dry and warm the soil. Farmers let off surface water from their wheat, but very few think it worth while to let off water from land unoccupied with crops. If they would do so, they would frequently be able to plow and work the land a week or ten days earlier in the spring."

Hints and Helps for Farmers.

A COMBINED ANVIL AND VISE.—It is rarely that we meet with so useful and cheap a tool, as the combined anvil and vise shown at figure 1. On the farm there is almost daily use for it, in the shop it will be in constant requisition, and in the house

Fig. 1.—COMBINED ANVIL AND VISE.

the smaller sizes will often be found handy. When we can have two good tools in one, without depriving either of any of its value or effect, there is a gain. An anvil and a vise have a natural relation to each other, and it is a happy instance of ingenuity that has united these in one tool. The makers are the Richardson Manufacturing Co., of Worcester, Mass. The smallest size weighs 14 lbs., and the largest 40 lbs.

A CORN HARROW.—"J. R.," Livingston County, Illinois, sends us a sketch (fig. 2) of a harrow of his own make, with which he has harrowed corn very successfully. It is made in three sections, the bars are 14 inches apart, each section is separate, and moves independently, so that one can be lifted and freed from obstructions

Fig. 2.—A USEFUL CORN HARROW.

without touching the others. This enables the harrow to ride over rough ground without missing the hollow places. The long bar is of 2 x 4 inch timber, and 12 feet long; the short bars are of 2 x 2 1/2 inch timber, and are 5 1/2 feet long. There are 60 half-inch steel teeth. The harrow will cover 3 rows of corn at a time, and has been used last season for harrowing the young corn four times. The same correspondent also sends a sketch of

A FIELD ROLLER.—A very good field roller may be easily made at this season, when timber is being cut, from a but-log of an oak-tree, in the form shown at figure 3. The log need not be a very large one, because the frame, in which it is mounted, enables it to be loaded to any reasonable extent, and

Fig. 3.—HOME-MADE ROLLER.

the driver may ride upon it, and thus add to the weight. A roller will be found very valuable in the

spring, when repeated frosts heave the ground, and throw out the winter grain. It may also be used with advantage during an open winter, when the ground is dry, to press back the plants, that have been lifted by a thaw, into the soil again. But it should never be used when the soil is wet.

DIGGING DITCHES.—Having been engaged the past winter in clearing and draining a piece of swamp land, for the purpose of having the ditches shaped properly, and of the proper size, we furnished the workmen, who were digging by contract, by the rod, with a frame made of laths, and of the exact size of the section of the ditch. This was 2 1/2 feet wide at the top, 1 1/2 foot wide at the bottom, and 2 feet deep, and a drawing of it is shown at figure 4. To level the ground, after the brush had been cut and burned off, we had a heavy hoe made in the shape shown at figure 5. This tool was very effective in cutting the roots of brush, the tussocks of grass roots, and leveling knolls into the hollows.

Fig. 4.—FRAME.

Fig. 5.—HOE.

The open winter has been very favorable for such work, and by the use of this hoe, the ground is leveled and put in good order for seeding with grass, very quickly and cheaply.

WORK FOR BAD WEATHER.—Our ingenious correspondent, L. D. Snook, of Yates Co., N. Y., sends us a number of sketches of useful devices, which will furnish both matter for consideration, and work for the wintry March days for those who find it desirable and convenient to make any of these handy contrivances. At figure 7 is a movable picket fence, which consists of panels made as shown in the engraving, and fastened by wires to short posts driven into the ground. Figure 6 represents a very convenient device for holding firewood, while it is being sawed with a cross-cut saw. The long piece of wood is placed in the bed formed by the cross-sticks, and is firmly held while each length is sawed off. The stakes should be placed as far apart, as the length of a piece of stove-wood, so that the cut can be made between each pair. A cover for a watering trough is shown at figure 8, which is devised to

Fig. 6.—HOLDING WOOD FOR SAWING.

prevent the fouling of the water by trespassing animals. The cover is made of a board strengthened by cross-cleats, and hinged at each end to the trough. A handle, made of hard wood, and two feet long, is fastened to the upper side of the cover. When this is pressed down with the foot, the cover is raised, as shown by the dotted lines, and the stock can be watered. If necessary, a slot is cut in the cover, to avoid interference from the spout of the pump. When the animals have been watered, the handle is released, and the cover falls by its own weight.

PATTERN FOR A CHEAP IRON GATE.—"S. H.," Belleville, Ohio, wants a pattern for an iron gate for barn yards, to be hung upon stone gate-posts. At fig. 9 we give a very simple wrought iron gate, which would be serviceable, durable, and cheap. It is made of bars of iron 1 1/2 inch wide, and a quarter of an inch thick, bent as shown in the engraving, and having holes through which the bars of half-inch iron are passed. The bars are secured at each end by nuts and washers, or they may be riveted. A diagonal brace is fastened in the same way, and this may be drawn up, to raise the gate,

if it should sag, by turning the nut at the upper end. Wrought iron hinges, and latch, are provided.

CASTOR POMACE—A RICH COMPOST.—We have recently turned over one of the richest compost-heaps we have ever made. It consists of castor-oil pomace, manure from the poultry-house, sods from road sides, mud from ditches, and earth from the surface of a yard in which cows have laid at nights during the summer. One ton of the castor pomace was procured from a mill at St. Louis, and this was found so strong that it was quite sufficient to raise a very active fermentation, and a great heat in more than twenty times its bulk of other materials. The heap has been turned twice, and each time the heat has arisen, and an excessively strong smell was given off, until several inches of fresh earth was thrown upon the heap. It is now in fine condition for top-dressing, or the heap of at least 20 tons will

Fig. 7.—PORTABLE PICKET FENCE.

make a rich fertilizer for 20 acres of corn at the rate of one ton per acre, applied in the hill. The whole cost of castor pomace, and freight, from St. Louis, amounted to \$18, (bags included), the other

Fig. 8.—COVER FOR WATERING TROUGH.

materials have cost only a little labor, so that one dollar a ton will cover the actual cost. We estimate the value of the compost as at least five times that of an equal weight or bulk of ordinary stable manure, which would cost not less than \$2 per ton.

RECLAMATION OF A SALT MARSH.—Reclaimed salt marsh is valuable land for meadows, as well as for cultivated crops. Some of the most fertile fields in existence were formerly useless salt marshes, or overflowed land. By drainage and freshening, the rich soil is fitted to bear any kinds of crop. To encourage this profitable work of improvement, the Massachusetts Society for the Promotion of Agriculture offer some handsome prizes, varying from \$500 to \$25, for the best reclaimed tracts of salt marsh from 100 to 5 acres. The work may be

Fig. 9.—AN IRON GATE.

begun at any time, but must be finished by 1881, as the prizes will be awarded November 1st of that year. Particulars may be learned of E. N. Perkins, Secretary, Pemberton Square, Boston, Mass. The entries must be made by April 1st, 1878. Much

valuable information in regard to the drainage and reclamation of such marshes, with the construction of banks, ditches, and sluices, and the after cultivation of the land, is given in Stewart's "Irrigation for the Farm, Garden, and Orchard," published by the Orange Judd Co.; price, \$1.50; sent post-paid.

A Portable Slop Barrel.

A barrel, mounted upon wheels, as shown in the accompanying engraving, will be found useful for

Fig. 1.—PORTABLE BARREL FOR SLOPS.

many purposes about the farm, garden, or household. The barrel is supported upon a pair of wheels, the axles of which are fastened to a frame which is connected with the barrel by means of straps bolted to the sides. The frame may be made of iron bent in the form shown at figure 2, or of crooked timber having a sufficient bend to permit

Fig. 2.—PLAN OF FRAME OF BARREL.

the barrel to be tipped for emptying. A pair of handles are provided as shown in the engraving. When not in use, the barrel rests upon the ground, and may be raised by bearing down upon the handles. The barrel may be made to rest in notched bearings upon the frame, so that by raising the handles, the wheels may be drawn from beneath the barrel, and the latter left in a convenient place until it needs removal. Figure 1 shows a side view of the barrel and frame complete. This contrivance will be useful for feeding slops to pigs, or for removing the waste of the house to the barn-yard.

A Table for Working Butter.

The increasing and profitable demand for a good

Fig. 1.—TABLE FOR WORKING BUTTER.

quality of butter put up for use, in acceptable forms, renders it desirable to have every facility for preparing the butter for sale in the best manner. Cakes, or pats of one pound, and half a pound, are the most popular, and the fancy seems to be inclined to a somewhat different shape from the ordinary round ones. Square cakes are not desirable, nor are they free from the serious objection that the moulds in which they must be made are not easily kept clean; it is best to avoid sharp corners

Fig. 2.—PADDLES.

in all dairy appliances. A compromise between square and round moulds may be reached by having them hexagonal or octagonal, and both of these forms are very popular. As the cakes have to be moulded and pressed, a properly furnished table will be found convenient for this purpose. Such a table is shown in figure 1, and can be made for a few dollars by any carpenter who sees the engraving. It is an

ordinary table, about five feet long, having room for a butter-bowl, scales, and presser. The butter is taken from the bowl, with the paddles, shown at figure 2, one of which is grooved on the face to prevent the butter from slipping off, and the other is smooth and sharp at the edges, so that it may be used for cutting as well as roughly forming the cake after it is weighed. These paddles may be made of white-ash or cherry wood. As the butter is weighed, it is worked with the paddles into a block that will nearly fit the mould, shown at figure 3. The mould is open at both ends, and should be placed, to be filled, upon the small platform, shown on the table. The follower (fig. 4) is placed upon the butter, and the foot being pressed upon the lever beneath, the mould is forced up against the top of the frame above it, and the cake is thus formed into proper shape; after which it is forced out of the mould by pressing the follower with the hand. A pail of fresh cold water should be kept at hand, and the mould, paddles, and platform should be kept wetted during the operation, by which the butter is kept from adhering to them.

Fig. 3.—MOULD.

4.—FOLLOWER.

Sales of Hereford Cattle in England.

The Herefords are one of the old established standard breeds in England, where fashions do not change so suddenly as with us. There are many herds in that country which have been bred with care for scores of years, and a few that have been kept intact for even a full century. Occasionally the surplus of these old herds is sold off, and farmers and breeders seize, with great alacrity, the opportunity of procuring breeding animals. Prices rule high at these sales, and maintain great steadiness; they are therefore a fair criterion by which the value of the stock may be estimated. At some recent sales, the following prices were realized, viz.: cows \$685 to \$760 each, and bulls averaging \$283; one yearling bringing nearly \$700; this was at a sale of a herd belonging to Mr. Tudge, a careful breeder of wide reputation. At another sale a number of yearlings brought \$205 each. At a sale of a high class herd, which included a bull that has taken 14 first prizes in 4 years, the champion prize against all breeds at the Royal Agr'l Society Show last year, and 6 special prizes, the prices realized were much higher. This bull brought \$1,330; yearling bulls brought \$135 to \$360, and one 3-year-old bull \$1,265. Several other sales have occurred, at which there was very active competition for the bulls, showing that this breed is much desired for crossing; the most profitable use that high-bred animals can serve for the farmer or the grazier.

Plan of a Grist Mill.

Although the general appearance of a grist mill is quite familiar to most persons, and especially to farmers, the internal arrangement is by no means well understood. There are many millers and mill-

wrights too, who, though long used to old-fashioned country mills, are not aware of the many modern improvements and conveniences that have been introduced into the business of milling, nor of the great facility with which mills can be furnished, complete, from the main gear for conveying power from the water-wheel or steam engine, to the smallest detail, including screws, and nails, with which the parts are put together. Recently we examined a specification and plan for completely furnishing a grist mill, which were made by the Bradford Mill Company, of Cincinnati; the specification includes all the gearing, shafting, stones, and their furniture, feeders, hoppers, bolts, bolting chest,

Fig. 1.—MILL STONES AND GEARING.

elevators, smut machine, belting, and all other accessories of a mill. The plan (fig. 2) shows the arrangement of a mill thus furnished, and is a sufficient guide for the erection of the building itself. The building is of two and a half stories, the ground floor is 12 feet in the clear, the second story 10 feet, and the half story 3 feet at the eaves. The burr stones, with their husk and gearing, are on the lower floor. The stones and gearing are shown separately at figure 1. The second floor contains the bolt, *D*, and gearing; the wheat bin, *J*, and the corn bin, *K*. The smutter and separator, *E*, is on the top floor; the elevator which conveys the wheat from the lower floor to the smutter adjoins the latter, and the cleaned wheat escapes by the spout upon the other side into the bin, *J*, from which it is fed to the stones below by the spout above them. The elevator for the corn is at *H*, and the elevator for the meal, *I*, adjoins it. The stones are driven by the pulley, (marked 2,) which makes 174 revolutions per minute; the upright shaft (3) makes 130

Fig. 2.—PLAN OF GRIST MILL.

revolutions per minute; the horizontal shaft (4) which works the smutter, corn elevator, and bolt, revolves 41 times per minute; the upright shaft (5) which drives the bolt makes 30 revolutions, and the horizontal shaft (6) driving the wheat and flour elevators turns 41 times per minute, being worked by a belt from the shaft, (4.) This arrangement is

simple and compact, and answers admirably for a small country custom mill, where wheat, rye, buckwheat, corn, and mixed feed are ground usually.

Barns without Beams.

The frequent use of the horse-fork and hay-

Fig. 1.—SECTION OF BARN.

carrier, renders it desirable to avoid cross beams in the barns, as these prevent the convenient movement of these implements. Formerly it was necessary to have the hay mows so low that a man could easily pitch the hay on to it from a wagon. This made it necessary to have the barn long and wide, in order to secure sufficient capacity. The roof is the most costly part of a building, and as the wider the roof, the stronger the frame must be to sustain the weight, the old-fashioned style of barn was very costly. The machinery now in use for handling hay, enables us to avoid the extra cost of building, and long, high, narrow barns are found to be more convenient, in many cases, than the low, broad, and short ones. But to construct a barn without cross beams to support the sides and roof, is a difficult problem for the ordinary builder, who does not understand the nature of truss work, and the immense strength gained by skillful use of comparatively very light timber. The airy, web-like railroad bridges, which combine strength with lightness and elasticity, and the ordinary balloon frame houses, are examples of truss work, and there is cer-

Fig. 2.—SECTION OF COW-HOUSE.

tainly no reason why this principle of construction should not be made available for farm buildings. Some time ago (August No., 1876), we illustrated an

Fig. 3.—VENTILATOR FOR ROOF.

octagonal barn, in which there were no cross-beams, and we now give some examples of barns of ordi-

nary shape, without cross-beams, and with roofs made on the principle of the truss. The section, fig. 1, is that of a Danish barn, illustrated in the "Journal of the Royal Agricultural Society," of England. The mode of construction is shown very clearly by the engraving, it being only necessary to point out the longitudinal timbers, which are shown by the dark shaded parts, and the manner of securing the roof timbers to the walls, which is done in an ingenious manner. The \neg shown by the dark lines in each wall, is an angle-iron, built into the masonry, by which the strut is fastened to it. At figure 2 is a section of a cow stable, built above where the fodder is stored, somewhat on the same principle. The arrangement of the stable below is also worthy of notice. The central passage is the entrance-way for the cows, with a manure gutter on each side, in the rear of each row of stalls. The feeding passages are on the outside, and the cows are fastened by chains, which slide on the irons seen on the sides of the stalls. A ventilating shaft (A, fig. 2) is carried up from the stable, through the floor above, and out through the roof. This is divided so as to form four distinct shafts, through which cold pure air can descend, as well as hot foul air can ascend. The section of the shaft, and the upper extremity above the roof, are shown at figure 3. The

Fig. 4.—FRAME OF LIGHT TIMBER.

framing of the roof is simple, light, and strong; the roof is covered with straw thatch, shown by the thick, dark, shading. At figure 4 we give a method of a similar construction by means of light timbers fastened together with bolts. The walls are of stone or brick, and if thought desirable, these may be strengthened by buttresses wherever the roof timbers exercise the greatest thrust. The main timbers are intended to be 3x10, the braces 2x8 or 3x6, as may be thought proper. Cross girts may be used wherever needed to stiffen the roof. The ends of the main timbers should rest in iron shoes fixed to the wall by angles and bolts. The form of a shoe that would be useful to sustain the weight of the timber and its load, is shown at figure 5. This may be cast or may be made of wrought iron. The building is intended to be 36 feet wide; the walls 12 feet high; the main roof timbers 20 feet long, and the cross-beam at the top 24 feet long. The machinery for carrying the horse-fork will be suspended to this beam in the usual manner.

5. SHOE FOR BEAM.

Mutton Breeds of Sheep.

People are too apt to be misled by appearances. This has been the case in regard to the magnificent, large-bodied, long-wooled, Lincoln, and the equally fine, though lesser, Leicester sheep. Western farmers, in some cases, and many Eastern farmers, have been misled by the appearance of these sheep into the mistake of trying to keep them. Some notable instances have occurred in Colorado, Kansas, Nebraska, Minnesota, and other Western States. In every case within our knowledge, these

large sheep have come to grief, and the experiment of keeping them has failed. The conditions are not favorable for them. They have been bred and hitherto kept under totally different circumstances. Their native English climate is free from the great and sudden changes to which ours is subject. There, these sheep experience none of the torrid heats and drouths of summer, nor of the severe dry cold of the winter. Their food is rich, plentiful, and succulent; roots, rye-grass, and oil-cake, have been the food upon which they have been built up, and here we have not that kind of food to supply them, or at least it is only in rare cases that such food is provided. Where large-bodied long-wool sheep are fed and kept in a manner according to their needs, they thrive well and are profitable to their owners. We have seen a flock of such sheep sold in the New York market at prices that were satisfactory and remunerative. A lot of sheep of this kind, 160 in number, which was recently sent from Canada to New York for sale, averaging over 160 pounds in weight, some of them reaching 300 pounds—and brought 6½ cents per pound live weight. If this can be done in Canada, it can be done in many parts of the United States, and probably anywhere, where the summers are not too hot and dry for their comfort, and the profitable growth of rich fodder and root crops. Elsewhere we do not believe disappointment can be avoided with this class of sheep. The choice of breeds of mutton sheep is large enough to meet all the requirements of those who wish to keep them. The Cotswold, Shropshire, Oxford Down, Hampshire Down, South Down, and the grades of these breeds, taken probably in the order in which they are named, are all excellent sheep in every respect, being hardy, not too exacting in the way of housing and feeding; and will thrive upon mixed farms where they can be supplied with fresh green fodder, roots, and fair pasture. Where these requirements cannot be met, these sheep should not be kept, but fine-wools and half-breds will be preferable. The keeping of sheep can hardly fail to be profitable when judgment is exercised in their selection and they are skillfully managed. But, as in other things, unless this business is well done, it had better not be done at all, because if profit is not made, there will be a loss. If a flock is not kept in good condition, it becomes bad altogether; in sheep-husbandry, one must either swim or sink, and nothing runs down so fast as a flock that is neglected or badly managed. On the same day, when the Canada sheep, before mentioned, were sold at an average of more than \$10 per head, some poor natives were sold at 2½c. per pound, bringing about \$1.50 each. The shipper of these, and probably the feeder, must have lost money; it is certain that there could be no profit in such sheep, and at that price, when freight and expenses are paid. An example of this kind will help to point the moral we endeavor to enforce continually, in this as in all other matters pertaining to farm work, viz.: that it is only the best work that pays, and that live stock must be selected judiciously, and in reference to all the peculiar circumstances of each individual and of each locality.

Keeping Pure-bred Stock.

Many farmers have made the mistake of trying to keep and breed a herd, or flock, of pure-bred animals, and have, through their frequent failures, brought discredit upon such stock. Pure-bred stock, as a rule, are not profitable for farmers. They cost too much; no farmer can afford to pay \$2,000 to \$3,000 for a herd of 10 pure-bred cows. They are used to careful tending and high feeding, and their product is no greater than the average of good grades of these breeds. "We know of no herd of pure-bred animals in existence, that would pay its cost of purchase and keeping by its product of milk, butter, or meat, alone; it is only by the sale of animals for breeding that the profit is made. But admitting this to be true, pure-bred stock are not, for this reason, to be considered of less value. If we have not the pure stock, how can we procure the grades, which are found so profitable? Grades, of high character, are the most profitable farmers'

cows. Experience proves this to be so in every case. A most notable instance of it is found in the herd of Mr. Thomas Fitch, of New London, Conn., who has been engaged in crossing the Jersey upon every other breed, including what are known as "native" cows, for more than 30 years. This breeder keeps a herd of choice pure-bred animals, descended from the old-fashioned importations, made when the butter product was more thought of, than black points, solid-color, or other fancies, for the purpose of raising grade cows of large producing capacity of rich butter. Probably no breeder in the country has been more successful in his line, and his success is an example for farmers, which proves that it is best to choose one breed with which to improve his native stock, to adhere to that, gradually grading up his herd, and selecting only the best to breed from. One pure bull, which may cost \$250 to \$300, will sire, during his vigorous period, at least 50 calves, thus adding a small trifle to the cost of each over that of a calf from a common scrub bull. By adhering to one breed, there is a certainty of arriving at a definite result very soon; but by the too frequent habit of changing every two or three years, no satisfactory result is gained, and after a life-time of futile effort, the farmer ends where he begun, and berates pure-bred stock as the cause of his failures. As with cows, so with sheep, swine, and poultry. The pure breeds are not found profitable to keep, except for their services in raising grades, and in keeping up a supply of breeding animals for this purpose. In this way a farmer, who can afford it, may be justified in purchasing two or three pure-bred animals for improving a herd of good natives, and if he uses these with skill, he may find it very profitable.

The Use of Horse Powers.

We do not know of any farm machinery which pays a better profit on its cost, or is of greater convenience than a horse-power and threshing machine. To thresh by hand and the flail may be advisable under some unusual circumstances, such as at the present time when manual labor is very cheap, and it is desirable to find employment for worthy workmen during the winter; but in general it is imperative that this and other work be done out of hand, so that other jobs may be attended to. For this purpose nothing is more convenient than to have a horse-power and attached machinery in the barn which can be put to work at an hour's notice. Besides when the weather is stormy and unfavorable for out-door work, the threshing, wood cutting, or fodder cutting, may be done in-doors without the employment of any outside labor. Three persons, one man and two boys, are sufficient to work a thresher with a two-horse tread-power, and these can thresh in one hour as much as one man can beat out with a flail in a whole day.

The principle upon which a tread-power is made to operate, is that of the inclined plane, which is one of the so-called mechanical powers. In one sense the effective force is gained by means of the weight of a falling body. In this case the weight is that of the horses, and if the team weighs 2,000 pounds, and the inclination of the moving floor of the machine is $1\frac{1}{4}$ foot in 10, with a speed of 220 feet per minute, or about $2\frac{1}{2}$ miles per hour, we have two horse-power, or the equivalent of 66,000 lbs. raised one foot high per minute. This may be shown as follows:—At the speed and the inclination mentioned, the horses traveling 220 feet per minute, would raise themselves exactly 33 feet high in that time, if the inclined plane were stationary and long enough, and weighing 2,000 pounds, they actually raise what is equal to $2,000 \times 33$, or 66,000 lbs., one foot high; but as they descend on the inclined plane as fast as they walk, they in reality create a power equal to a body weighing 66,000, falling one foot per minute, which is precisely two nominal horse-power. It is evident that the total effective force utilized in work depends upon the excellence of the machine, and it is just here that the principle of the railroad-tread powers is noteworthy. The structure of these machines is such that friction, which is destructive of power, is reduced to the

least possible amount. The traveling bed runs upon wheels which move in a smooth metallic track, thus preventing any more than the least possible friction or waste of power. The whole weight of the horses is employed to the best advantage, and if the machine is used in a careful manner, and accurately set up, with both ends perfectly level, kept clean, and properly oiled, there is a very small loss of power. We have used one of these powers for several years with great satisfaction, and without finding the work to be at all severe upon the horses—in fact, it is much easier than work in a mowing machine. When inclined to take the work quietly, we have used only one horse in a two-horse power, changing horses at noon, for either threshing, sawing wood, or cutting fodder. A great variety of these useful machines, both for one-horse and two, is offered to those who need them. While there are differences in their style and make, which may go to influence the choice of a purchaser, yet we can hardly say that there is any great preponderating excellence in any one over all the others; and if there is one that is in any respect inferior to another, we can justly say that the least effective machine made is of sufficient value to satisfy any farmer that he has the worth of his money in exchange for it. Among the manufacturers of these machines worthy of notice in different localities, we might mention Wheeler & Melick Co., Albany, N. Y.; Minard Harder, Cobleskill, N. Y.; A. B. Farquhar, York, Pa.; B. Gill & Son, Trenton, N. J.; G. Westinghouse & Co., Schenectady, N. Y.; W. L. Boyer & Son, Philadelphia; New York Plow Co., New York, (who make a one-horse-power), and A. W. Gray & Sons, Middletown Springs, Vermont. In another portion of the *American Agriculturist* the special points of both horse powers and threshers are set forth and illustrated by engravings, and whichever of these machines may be selected for purchase, it will be found that the manufacturers not only have a high reputation, but by the excellence of their wares are desirous of deserving it.

EFFECT OF BONES ON DAIRY FARMS.—As an evidence of the great value of a dressing of bone-dust upon dairy farms, we have the testimony of an English agricultural writer of high repute, and the author of a Royal Agricultural Society's Prize Essay. This gentleman states that since bone-manures have been applied to the Cheshire pastures, the product of the soil in herbage and cheese, has been greatly increased; in many cases having been actually doubled. The increase of stock kept in the locality has been from 30 to 50 per cent, and in one case, of a farm of 160 acres, the number of feeding stock has been enlarged from 20 cows and 3 colts, to 35 cows, 8 feeding heaves, 16 yearlings and heifers, 5 horses, and 3 colts. But at the same time it is true, the quality of the cheese has been, to some extent, deteriorated, except where the most skillful management has been applied to the manufacture; the richer herbage being found to produce milk which requires the greatest care and skill in every step of its manufacture into cheese.

Portable Poultry-Houses.

Poultry-houses that may be moved from one place to another, could be made useful in gleanings grain fields, in clearing newly-plowed ground of insects, and in other desirable ways. A movable poultry-house is by no means novel, it having been described and used years ago. A French author on galliniculture, Geyelin, described one many years ago, which was used in grain fields to gather the scattered grain after harvest. This was constructed something like one of those vans used in transporting animals kept in traveling menageries. It was 20 feet long, about 7 feet wide, and the same in height. A set of steps was fixed at one end for the fowls to enter and leave, and nest-boxes and roosts were provided within. Several of these houses were drawn to the field, and one of them was furnished with a small apartment for the keeper who attended to the fowls. A large number of fowls could be accommodated in one of these houses, as they were intended to be cleaned daily, and the

droppings scattered upon the ground around them as they were moved from place to place each day.

A description, with drawings, of a useful porta-

Fig. 2. GROUND PLAN OF PORTABLE POULTRY-HOUSE.

ble house, has been sent to us by A. R. Sproule, of Picture Rocks, Pa. These were made expressly for the *American Agriculturist*, and the design is not patented by Mr. Sproule, but is offered freely to our readers. A view of the house is given in figure 1, on next page. It is of wood, and, as will be seen, is mounted upon an axle and a pair of wheels. By means of a pair of levers, raised to the position shown by the dotted lines, the house is lifted, and made to rest wholly upon the wheels, so that it can be moved from place to place as desired. Figure 2 shows the ground plan, with the boxes for feed, water, and gravel. These are secured to the sills, and are kept clean by a sloping cover of small rods. The house is 10 feet long, by 5 feet wide, and as high as may be necessary. The nest-boxes, 16 inches square, and 4 inches deep, are secured to the upper corners of the enclosure, a small door being provided for reaching the eggs. The roosting poles are so arranged that the fowls can easily climb from one to another. Figure 3 shows a single section of the open work of the enclosure, nine of which are used in the structure. This is made of oak rods, and rails, which are bored to receive the rods. Any cheaper method of construction may be used.

How the House is Made.

The size may be 5x10 feet, or 4x8 feet, and 5 feet high to the eaves. The sills are made of $1\frac{1}{2}$ x3 inch stuff, laid flat down, halved together at the corners, and nails driven through upward into the ends of the posts. The corner posts are 3x3 inches, the middle ones are 3x4 inches. Each is properly mortised to receive the rails of the open sections. A light cornice, or a $2\frac{1}{2}$ -inch band, is securely nailed around the top, a little above the eaves,

Fig. 3.—SECTION OF OPEN-WORK.

leaving sufficient room for the roof boards to pass under between the band and the upper rail. To the back side of this band is nailed the balustrade, each piece having its ends toe-nailed to the posts. A light ridge pole is attached at each end to the balustrade near the top, which forms a double-pitch flat roof. This is made of one thickness of $\frac{3}{4}$ -inch boards, the same as the enclosed sides. The upper

section at the end, over the feed trough, is hung with hinges for a door, through which to place feed, etc. The levers have their fulcrum ends resting on the axle, and are bolted to it. About 12 inches from it, and opposite to it, and through the middle posts, are pivot bolts, on which the weight of the house hangs when the levers are being worked. Narrow strips are used as braces for stiffening the frame lengthwise, which are placed inside, also bits of hoop iron should be used about the corners to strengthen the joints. With these appliances, and proper tools, any skillful mechanic can complete the job. Its weight is about 300 pounds, and the house affords room for keeping from 12 to 24 fowls through the season. The advantages of such a house are that the fowls are under perfect control, and are kept quite as healthy as when running at large. Every morning, when the house is moved, there is provided a clean, fresh apartment, with fresh earth and grass. Fowls become thoroughly domesticated by being thus treated. Those that are inclined to sit, are put outside, they will hang about, and make an effort to get in, and the desire to sit soon passes away. The manure is all saved to the best advantage.

New and Wonderful Farm Seeds.

Our regular dealers—by our we do not mean New York City only, but the whole country—endeavor to keep well up with the times, and supply such seeds as have an established reputation, or which seem worthy of further trial. But aside from the regular dealers—men known in their trade all the way from Boston and other New England Cities, to Omaha and other Western localities—there seems to be a set of men at work with seeds not known in the

Fig. 1.—SPROULE'S PORTABLE POULTRY HOUSE.—(See page 99.)

regular trade; and they do not advertise them, so far as we have seen, in the well known agricultural papers. Our correspondence shows that these seeds are offered by mail, with very attractive terms to agents, and by the aid of circulars, which promise very largely. Indeed, if the statements in these circulars are true, the knowledge of the excellence of the seeds should not be confined to the few who receive them, but ought to be known to the whole farming community. Leaving other seeds out of consideration for the present, we give special attention to a grain which has turned up, under one name and another, during the last ten or a dozen years, as a

Wonderful Wheat or Rye.

In this article we do not propose to discuss the intrinsic value of the grain in question. That it may be useful in some localities is possible, if not probable. What we now wish to show is, that the grain is offered in a very peculiar manner under a variety of names, and in a way likely to confound and bewilder the farmer, who may come across the circulars of those who sell it, and who might wish to make a trial of it. Our first acquaintance with this particular grain was under the name of

Nevada Rye.

Some 10 or 12 years ago, we went, in company with our friend A. S. Fuller, now the competent agricultural Editor of the N. Y. "Weekly Sun," to

see a remarkable Rye at a commission house in the City. It was a clean and heavy grain, unlike any rye we had ever seen, and offered at \$10 the pint. Since then both Mr. Fuller and the writer, have kept the run of, and exchanged samples of this grain as it has come under different names. In the course of several years, we have received specimens of the same grain—that is, so far as external appearance, aided by the microscope goes, identically the same—from various parties, some times as rye, and at others as wheat. As follows:

Montana Spring Rye.	Diamond Wheat.
Montana Rye.	Wild Goose "
Russian "	Big Seed " or
Nevada "	Wheat of Taos.

As said before, we leave the question of the real value of the grain out of consideration. If it has any real value, the important point is, *what is the grain?* Is it Rye or is it Wheat? If Rye or Wheat, what is its proper name? Without troubling the reader by a relation of the steps by which we have arrived at the conclusion, we feel perfectly safe in giving it as our opinion that this many-named "Wheat" or "Rye," is simply the old, very old, grain known in Europe as Polish Wheat, *Triticum Polonicum*, and which has in Europe about as many different names as have been given it by the seed speculators in this country. This is a *distinct species* of wheat, and as different from the varieties ordinarily cultivated as *wheat*, as are the several forms of "Spelt" or "Speltz Wheat." We are so well convinced that this remarkable Wheat, or Rye, offered in this country under the various names given above, is the "Polish Wheat," or *Triticum Polonicum*, and nothing else, that we give an account of

The Polish Wheat.

which would seem to be a misnomer, as it is of African origin, and has been cultivated in Egypt and other portions of Northern Africa from very early times. In France, so unlike is it to any ordinary wheat that it is known as *Seigle d' Afrique*, or "African Rye." According to Klippart, in "The Wheat Plant," this species is known in Europe as Wallachian, Astrachan—and Egyptian Corn, Gounner, Symaker, Silesian, Cairo, and Double Wheat, in Germany; as Blé (wheat) d' Egypte, Blé de Surinam, Blé de Magador, Blé de Pologne à Epi Divariqué, in France, Fromenta di Polonia in Italy, and as Trigo di Polonia in Spain. He mentions four varieties, and Madame Vilmoren, who wrote the very elaborate article on Wheat for the "Encyclopédie Pratique de l'Agriculteur," mentions its great tendency to vary, and figures two of the most striking forms. We give here an engraving of a head of this grain raised in this country; it differs from the common wheat in the great size of its *glumes* and *palets*, or the envelopes which form the chaff; these are very large, and usually have very long awns, or bristles, though in some of the European forms these are much smaller, and there is probably the same variation in this respect that there is in our ordinary wheats. The grain of the Polish wheat is long and narrow, semi-transparent and horny in texture. When cut under the microscope, a grain of ordinary wheat is opaque and floury, but this shows nothing of the kind. We give in figure 2 a grain of this Polish wheat, by the side of a very good sample of common wheat, which serves to show their relative size and shape. We are

Fig. 2.

now, and all the time, in favor of the introduction of any *valuable* new seeds, whether of farm or garden crops, and will do all that we can to make all meritorious things—wherever they may originate—known to our readers. But we have the right to insist—on behalf of the farming community—that these "novelties" shall be introduced under their proper names. When Mr. Osment, of Bradley Co., Tenn., offers as "Something New," "Our Big

Seed Wheat—Wheat of Taos,"—"Taos" being the one-horse-est of all the "one-horse" towns in New Mexico,—and Mr. Tipton, of the same Co., Tenn., offers "Diamond Spring Wheat," "claimed to be imported from Chili," and when we compare the "Big Seed Wheat," and the "Diamond Spring Wheat" under the microscope, and can not tell "one from t'other, or t'other from which," we begin to think that the seed business in Tennessee is rather mixed. Moreover, when we take Tipton's engraving of his "Diamond Spring Wheat," with the stalk end pointing to the right hand, and place it over Osment's cut of "Big Seed Wheat," with the stalk end at the left hand, and hold them up to

Fig. 1.—POLISH WHEAT.—(*Triticum Polonicum*.)

the light, and find them to be one and the same engraving, we wonder—yes, very much do we wonder—that two such remarkable wheats should be so much alike. But our wonder as to the wheats of said Osment and Tipton is as nothing, when we contemplate their corn. What wonderful seeds these Bradley Co. people have! We do not propose to advertise them until we have tried their corn, of which we have a supply from headquarters, but when their corn gives us, according to circular, "from 4 to 14 large size ears on every stalk," we shall gladly announce the fact. In the meanwhile, we advise farmers in general to touch all these wonderful seeds gently. With these, as with all other novelties, we say—*go slow*. If disposed to test them, invest only what you can afford to lose. If they prove to be of any value, a small sum should give you enough to supply you with seed for another year.

Alpine Plants for Common Gardens.

Those who have visited high mountain regions in any part of the world, must have noticed the

SCARLET WIND-FLOWERS.—(*Anemone fulgens*.)

abundance and brilliancy of the flowers which grow in those elevated localities. The plants found in these places have generally a low habit, pleasing foliage, and abundant and often brilliant flowers, which are all the more attractive on account of their dreary surroundings. Several works have been written upon Alpine plants (the best of which, Mr. Robinson's, was noticed a few months ago), and some catalogues make a special list of such plants, and both works and catalogues indicate, that while there are some Alpine plants that can only be satisfactorily cultivated when their native locality is imitated by an artificial rock-work, there are many others that will flourish in the ordinary garden. Some of our native plants that are never found growing wild except in wet and swampy localities, when taken to the drier and rich soil of the garden, flourish quite as well as, if not better, than in the wild state. So, many of those plants that naturally grow only in Alpine regions, make themselves quite at home in our garden borders. The term *Alpine*, as applied to cultivated plants, is one not easy to define. While some of the natives of high regions are very difficult to manage, and can only be successfully cultivated when the peculiarities of their natural habitats are imitated, others, and perhaps the majority, will flourish in the ordinary border, especially if they have a mulch of stones to prevent their roots from drying out. As an illustration of this: One of our associates several years ago went on an expedition to the Rocky Mountains. As occasion offered, he sent home roots by mail; they came without labels, and all we knew of them was, they were plants from the Rocky Mountains. We had boxes filled with an open soil, set out the roots, and then paved the surface with stones from the size of a walnut, upwards. Of course these stones acted only as a mulch, but they saved many of the "Alpine" plants. Experience has taught us one thing about these plants: If the natural locality of a plant is "Alpine," that it is no reason that it will not flourish in our garden borders. We give here illustra-

tions of a few flowers usually classed as "Alpine," which may be grown in any ordinary garden.

The Scarlet Wind-Flower.

Our native Wind-flowers, or Anemones, especially the earliest, the Wood Anemones, (*Anemone nemorosa*), are noted for their delicacy of habit and of coloring, but the Scarlet Wind-flower (*Anemone fulgens*) of Southern Europe is quite the opposite of this. Instead of a modest habit and delicate color, it asserts itself in the most positive manner. Its flowers are erect, and the color of the most intense scarlet. As a general thing, the flowers of spring have delicate tints, but this shows the striking, vivid scarlet of the flowers of mid-summer. Travelers in Southern Europe and Western Asia, speak of the brilliant flowers of this species as appearing above the snow. The foliage of this plant is deeply lobed and toothed, and is of itself handsome; the flower-stems arise from this, in vigorous plants, a foot high, bearing flowers about two inches across, of the form shown in the engraving, and in color of a most intense scarlet, with which the blackish color of the stamens presents a strong contrast. No spring flower within our knowledge is so brilliant as this. It is one of those plants which were introduced many years ago, but for some reason fell into neglect, and within a few years has been revived as a novelty. It seems quite hardy, and aside from its utility as a border plant, it will no doubt prove excellent for forcing in greenhouse or window culture. In contrast with this most gaudy of spring flowers, is one with the botanical name of *Omphalodes verna*—the name *Omphalodes* means "navel-like," and refers to some resemblance of the seed to the navel. Its common name is

Creeping Forget-Me-Not, or Navel-Wort.

The plant is a native of the mountain woods of Europe, and has proved perfectly hardy in this country. Its common name, "Creeping Forget-me-not," indicates its relationship to the well-known "Forget-me-not," but it is quite unlike that in habit, as it creeps closely upon the ground, while it carpets with smooth, bright green foliage, from which arise numerous flower-stems about 6 inches high, bearing clusters of several flowers, each about 1/2-inch across, of the most intense blue, which is rendered all the brighter by the white spot, or

SEA CATCHFLY.—(*Silene maritima*.)

"eye," at the throat. It begins to flower in early spring, and in a moist locality will continue well into the summer. This promises well as a plant to carpet beneath shrubs, as its mat of foliage is pleasing, even when there are no flowers. Among plants usually classed as "Alpine," is one common in Western Europe on rocks and mountains by the sea,

The Sea-Side Catchfly,

which we had growing last summer, and were much pleased with. In making a collection of hardy herbaceous flowers, and testing about everything that

CREeping FORGET-ME-NOT.—(*Omphalodes verna*.)

promises to be desirable, we have frequently come across some very old plants, which, as we had not happened to grow them before, had to us all the interest of novelties. This was the case with the Sea-side Catchfly, *Silene maritima*, a native of the sea coast of Great Britain, and one of the oldest of garden plants. Still, when its tufted mats of foliage, were studded all over with little white flowers, it was just as pleasing as if it were the latest introduction from some far country recently for the first time explored. Wishing to know on what part of the British coast this grew, we consulted Bentham's "Handbook of the British Flora," and found that he regarded it as merely a sea-side form of the Bladder Campion, *Silene inflata*, a plant found in New England and New York to Pennsylvania, as an introduced weed. The habit and general appearance of our garden *S. maritima*, is so unlike that of *S. inflata*, that we were surprised to see it thus disposed of, and looking to see what other botanists had done with it, we found that while some agree with Bentham, others, and among them Hooker, regard the sea-side plant as a distinct species. So far as garden qualities go, the two plants are abundantly unlike. The Sea-side Catchfly forms dense turf-like masses of glaucous foliage from among which arise the stems bearing one to four pure white flowers; the calyx is inflated or bladdery, and the petals deeply notched in the middle, each with a large scale, and these scales together form a crown at the throat of the flower. The engraving, of the natural size, gives an idea of the flower, but does not show the mass of foliage. It is one of those accommodating plants that will grow almost anywhere, and is always pleasing for its neatness, and the abundance of its bright white flowers, which bloom nearly all summer. For

materials to make engravings of these plants, we are indebted to Messrs. Woolson & Co., Passaic, N. J., who make a specialty of Hardy Herbaceous and Alpine plants. The illustration of *Anemone fulgens* is from a plant forced for the purpose, showing that it will be useful for greenhouse or window culture. The same is true of *Omphalodes*

verna, of which Robinson, in his work on "Alpine Plants," says: "Tufts of it taken up and forced in mid-winter, form beautiful objects in pots or baskets in the conservatory." Of course, whatever may be done in the "conservatory," may be accomplished by the careful window gardener. Those who cultivate window plants, may derive much pleasure from forcing the common plants of the garden. If these, such as *Dicentra spectabilis*, ("Bleeding Heart"), *Astilbe Japonica*, often called *Spiraea*, and even such low-growing shrubs as *Deutzia gracilis*, *Spiraea Thunbergii*, in fact, any of the early flowering herbaceous plants or shrubs, are potted in autumn and brought to the window in February, they will flower abundantly, and when done may be set out in the border to recuperate.

A Pruner for Blackberry Bushes.

The annual cutting away of the old canes of blackberry, raspberry, and other prickly plants, is

Fig. 1.—BLACKBERRY PRUNER.

not a desirable job, and with the ordinary pruning knives and shears, one is quite sure to come out of the battle well scarred. Several pruning knives for this work have been contrived, and we have illustrated a number of them. We now give engravings of one designed by Mr. J. A. Umfreville, of

Fig. 2.—BLADE.

Rhode Island, who sends sketches of his contrivance, as a partial return for the many useful hints he has received from the *American Agriculturist*. Figure 1 shows the pruner complete; the rod is of 1/4-inch iron, and 30 inches long, with the blade at one end, and a handle at the other. The cutting portion, or knife, shown in figure 2, is made from an old saw-blade; it is 2 1/2 in. long, and 1 1/2 in. wide; the cutting portion is a triangular notch 3/4 in. across at the lower or open part, and the edges made very sharp. The cutter is attached to the rod by making in that a dove-tail notch, as shown in fig. 3. The cutter being placed in the notch, with the brass strip, fig. 4, over it, all are riveted firmly together by means of rivets put through holes made for the purpose. This is evidently a useful implement for pruning blackberries and similar shrubs; it is of course used with a sudden pull towards the operator, and needs to be, as an implement made after this pattern would be, very strong in all its parts.

Fig. 3.

Fig. 4.

What Strawberries Shall I Plant?

The strawberry is the fruit of the people. If one has room to raise no other fruit, he tries to find a place for the strawberry bed, knowing that freshly picked strawberries, ripened upon the vines, are about the greatest luxury that poor mortals can enjoy. When asked as to varieties 10 or 15 years ago, we could only answer, "plant the 'Wilson,'" for that was then the only one that one could set out with the hope of getting strawberries. The "Wilson" was a safe variety to plant, as one who had vines was very sure to pick berries—to be sure they required much sugar to make them eatable, but they were strawberries—and other varieties of the day gave but meagre returns. But matters have changed of late years, and we have several varieties, quite as sure to produce fruit as the Wilson, and fruit of much better quality. No fruit is more affected by the character of the soil than the strawberry. The stiff clay soil on the place of the late Mr. Knox, a few years ago known as the "Strawberry King," gave him results with the "Jucunda," and other foreign kinds, that no one else could equal. The truth is, that certain varieties are best for light soils, and others most suited for heavy soils. If asked to name the best one variety,

without regard to soil, the variety from which one would get fair returns wherever planted, we should say "Charles Downing." This is a far better fruit than the "Wilson," and apparently equally reliable. After an experience of several years, we are safe in saying, if we could have but one variety for family use, it would be "Charles Downing." For earlier varieties, "Downer's Prolific" for light, and "Nicanor" for heavy soils are to be commended. Among later varieties there are, for light soils, "Seth Boyden," "Green Prolific," and "Kentucky." For heavy soils, "Triomphe de Gand," and "Jucunda." Of course there are other claimants for popularity, such as "Col. Cheney," "Monarch of the West," "Great American," and others, which are worthy of trial, but we have given above those which have been tested for several years in a great variety of localities. We advise those about to plant strawberries, as we do those intending to plant vegetables: put in your main crop of well tested varieties, and then try of the newer kinds all you can afford to test. To novices in strawberry culture, we would say, a plant can not bear fruit until it has made one season's growth. If set this spring, and well cultivated, a good crop may be had next spring. If the plants are set in the fall, they give but a partial crop the next spring, and a full one the year following. If runners are struck in pots in June and July, and set out in August, as we have shown in former volumes, then a full crop may be gathered the spring following. For ordinary garden culture, the plants may be set a foot apart in rows 18 inches apart, in highly manured soil—the earlier, the better.

Protecting Plants in Spring.

As soon as the earth ceases to receive heat from the sun, cooling begins. The earth, when the supply of heat is withdrawn, begins to give off heat by radiation—the heat passing off into space, and when the surface becomes sufficiently cooled, the moisture in the air condenses, and we have dew or frost, as it may be. If we cover the surface with a mat, or board shutter, this cooling is checked, and if the mat or shutter is raised up on supports several feet above the earth, no dew or frost is deposited. The earth gives off heat as before, but instead of its passing off into space, it is received by the mat or shutter, and a good part of it is reflected to the earth again, and neither dew nor frost appear upon the space beneath. It is not necessary that the protecting screen be a mat or a shutter, as one of cotton cloth, or even of newspaper, will serve nearly as well. What is true of the effect of cooling upon the earth itself is equally true of the plants that are growing in it—indeed, these are more readily affected. When the upper layer of earth cools, the layer below imparts its heat to the upper one, and the cooling goes on slowly. The plants have not this reserve to draw upon, and cool much more rapidly. Even our hardiest plants can not make any growth when the temperature is too much reduced, and though the days may be warm, the loss of heat at night is so great that they remain stationary, while more tender plants, if not killed outright, are so chilled and checked in their growth that they never fairly recover. It is by avoiding these alternations of heat and cold that so much is gained by the use of cold-frames for lettuce and a few other plants, as described by Mr. Peter Henderson, on p. 63, last month. The earth within the frame, and also the plants, receive the sun's rays during the warmer part of the day, but in the afternoon, as soon as the heat of the sun begins to decline, the sashes are closed tight, and mats, or shutters, to prevent loss of heat, are placed over the glass. Our people seem very slow to avail themselves of the great advantages offered by cold frames, and wait for their lettuce, radishes, and early spring vegetables until they can be had in the open ground without aid; and they do not put out their tomato, and other plants, until settled warm weather. These remarks are not intended for market gardeners, who know that if they are to have early crops of any kind, they must "forward" them by every means within their knowledge, but for those who have private

gardens, and who, rarely, by complying with the conditions we have stated, have their spring vegetables, until long after they are offered for sale. The uses of the cold-frame were mentioned last month (besides Mr. Henderson's article) in the monthly Notes about work. Aside from the cold-frame, small frames, or what the English call a "hand-light," and the French, a "*cloche*," or bell-glass, may be made useful in every private garden. Even a frame a foot square and 8 inches high, with a piece of bleached muslin (cotton cloth) tacked over one end, will be found most useful. This, if

HAND LIGHT.

turned over a cluster or "hill" of plants early in the afternoon, and removed late in the morning, when the sun is well up, will often do wonders in the way of helping plants. Even later in the season, while the days are sufficiently warm, the nights are cool, and such a covering is of great use. Try a frame of this kind over a hill of cucumbers, or early squashes, and you will never be without a stock of them. The next step in advance, is to use the frame, but replace the muslin by a pane of glass,—in short, a very small cold-frame. We were led to these remarks by a note from "S. M.," Herkimer Co., N. Y., who sends us a sketch of a "plant protector" which he uses, and which is given in the engraving. Our correspondent writes as follows:

"Its merit consists in its cheapness; a few nails, a couple feet of 1/2-inch board, and a single pane of glass, being all that is required. The glass slides in grooves cut in the sides, and is held in position by the button. By turning the button, the glass may be moved downwards in the grooves, and held at any height by turning the button upward, so that it will press the under surface of the glass, and thus give the amount of ventilation desired. When it is desired to shade the plant, the high board back may be turned toward the sun."

"S. M." gives no dimensions; we have reproduced his drawing just as he sent it. The frame seems too tall in proportion to its width, and any slant greater than 45°, causes a loss of light. What we would impress upon our gardening friends is, the great utility of these small frames, which each one may build according to his notion, as we are sure that when once tried they will not be abandoned. They will be found useful in every garden, early in the season for early lettuce, cauliflowers, etc., and even still more valuable in protecting tomatoes, egg-plants, and other things that get "set-back" during our hot days and cool nights.

What may be Sowed with Clover Seed.

Some two months ago, in making up a circular to accompany the *American Agriculturist* Microscope, we indicated that one of its uses, and an important one to farmers, was, that it would enable them to carefully examine the finer seeds before sowing, and to distinguish the seeds of weeds from those of the crop. In the natural distribution of seeds, it would appear that the scattering of the seeds of weeds was most carefully provided for. But however abundantly these are disseminated by natural agencies, the careless farmer sows them broad-cast by the handful, and does what Nature can not do—he puts them in well prepared soil, where they will be sure to grow. To take an illustration in season. In this very month of March, hundreds of farmers will be sowing their clover "on the last snow," as many try to do. Next summer, or later, we shall have from some of these same farmers, letters and specimens. The letters will be to this purport: "A new weed has appeared in their fields, or meadows, threatens to kill out everything else; what is it, and how shall we get rid of it. It never was known here before this year—where did it come from?" Of course we shall try to answer each inquiry as well as we can. The where did it come from? we can answer now—"you carefully sowed it, that cool March day, with your clover

seed." In writing of the uses of the microscope, as above referred to, and feeling the importance of the matter, we were at considerable trouble, in hunting along roadsides and fence rows, to find some of the troublesome clover weeds, and get a few seeds to make an engraving from. After this had all been

done, we were quite surprised on receiving the "Journal of the (Eng.) Royal Agricultural Society," to find that the Botanist of the Society, Mr. Carruthers, had been

Fig. 1.—RED CLOVER.

at work on the very same matter, and in an article on "Clover Seed and its Impurities," had given engravings of the weed-seeds that are likely to be sown with clover seed in England, showing, magnified, 24 different kinds. It is a curious fact, that some of the most frequent weeds in European fields, do not become established here at all, while others, not especially troublesome there, find here conditions better suited to them, and are among the greatest annoyances of our farmers. Out of the two dozen weeds, the seeds of which are figured in the article referred to, we find hardly a dozen that our farmers find injurious. We gladly avail ourselves of Mr. Carruthers' engravings of these weed-seeds that our farmers should know and

Fig. 2.—WHITE CLOVER.

Fig. 3.—BLACK MEDICK, OR NONSUCH.

avoid, as it allows us to present the matter in time for the present spring sowing. The very general distribution of the *American Agriculturist* Microscope, will allow of the careful examination of seeds before sowing. This is one of those matters that need no argument; if the farmer does not feel its importance, and will not make a careful examination of his seed, if not before purchasing, at least before sowing, when the facts in the case are pointed out to him, no amount of talk will convince him that he should do so. We would not have, in a clover field, a single plant of Viper's Bugloss (fig. 9), for the price of many yearly volumes of the *American Agriculturist*, and its Microscope. Yet it yearly extending itself in several States.

To Examine the Seeds.

The quickest way will be, to take a sheet of white paper, and spread out a small quantity of the seed—say a teaspoonful or so. Then remove the glasses from the Microscope, and using the upper two glasses only, let the lowest glass, and the diaphragm serve as a handle. With the upper two glasses, go carefully over the whole surface of the paper covered by the seeds. First quite familiarize the eye with the appearance of the clover-seed itself. The seeds of all the clovers have a general resemblance, looking, when magni-

Fig. 4.—CHICKWEED.

Fig. 5.—SPURRY.

fied, like distorted beans, as seen in the two kinds most generally sown by our farmers; figure 1 being the Red Clover (*Trifolium pratense*), and figure 2 the White, or Dutch, Clover (*Trifolium repens*). The weed-seeds shown are magnified in the same

proportion as these. While it would be a great misfortune for a farmer to stock his fields with some of the weeds, the seeds of which are here given, other weeds are of less importance, their chief harm being in occupying the ground and preventing the clover from growing. If one buys and sows clover, he does not wish—for example—a crop of Spurry, a useful enough plant in its way. The engravings are sufficiently accurate to allow the seeds to be recognized at sight. Usually the

Fig. 6. The engravings are sufficiently accurate to allow the seeds to be recognized at sight. Usually the

Fig. 7.—OX-EYE DAISY.

Fig. 8.—PLANTAIN.

natural size of the seeds is shown (by dots, if small) by the side of the magnified figures. Figure 3 is Black Medick, or Nonsuch, (*Medicago lupulina*); the larger cut is the one-seeded pod, and the others the separate seeds. Not a bad weed, but occupies the ground to the exclusion of clover. Figure 4 is Chickweed, (*Stellaria media*), often abundant in moist grounds; not bad. Figure 5, Spurry, (*Spergula arvensis*), a quick growing annual, which will crowd out the young clover. Figure 6, White

Fig. 9.—VIPER'S BUGLOSS.

Bed-straw (*Galium mollugo*), a sprawling plant 3 feet long, now becoming at home here. Our "White-weed," or Ox-Eye Daisy, is shown in figure 7. Too well known in the older States; careless farmers say it does no harm. It simply prevents the growth of nutritious plants—and that is harm enough. Figure 8 is the Rib-Grass, not a grass, but the Rib-wort Plantain (*Plantago lanceolata*). Is abundant, and in England regarded as a good sheep pasture plant. But the clover-field is no place for it. Figure 9, Viper's Bugloss, Blue-Weed and Blue Devils, (*Echium vulgare*), already too well known in some of the older States—and should be stopped. Its seed, the largest of all these weed seeds, is readily recognized, and one of the very worst of all known weeds. When it takes possession, it comes to stay, and the farmer may step aside. Figure 10 is Self-heal, (*Brunella vulgaris*), of no special importance except as showing slovenly culture. Figure 11 is the seed of our well known Sheep Sorrel, (*Rumex Acetosella*), a sour weed on poor lands. Fig. 12, Common Goose-foot, or Lamb's-quarters, (*Chenopodium album*), altogether too well known, and wherever seen is occupying soil that should be growing something useful. But where is that worst of all weeds, the

Fig. 10. SELF-HEAL.

Fig. 11.

Canada Thistle? some will ask. The seeds of this are not mentioned as occurring in English clover seed, in the article referred to, and we have not seen it in any American samples that we have examined. Still, farmers should be on the look-out for it. In the descriptive sheet that goes with the Microscope is an engraving (fig. 10 of that sheet), showing clover and weed seeds, the long and narrow seed in that group is from an unripe specimen of Canada Thistle. That engraving also shows the seeds of the "Toad-Flax" (*Linaria vulgaris*), which is not included in the list of English weeds, but which is one of our most troublesome, and is spreading with unpleasant rapidity. Sow clean seed, and Canada Thistle and other pests will not trouble. In the Boys and Girls' Department there is something about preserving specimens of seeds, that some of the parents of the children may find of use.

Home Topics.

BY FAITH ROCHESTER.

New Neighbors.

I was very much pleased with the first call after I was settled in the last new home. It was evening, and Paterfamilias had just come from his day's work. The tea-tray, with his supper of baked apples, and bread and butter, had been brought into the sitting-room, and his cocoa was keeping warm in a little pail on the sitting-room stove. The little ones and their mamma find it more wholesome to have their light bread and milk supper earlier in the day. I would not have liked to receive a fashionable call just then, or a regular call of ceremony from strangers. But when answering the knock, we found a gentleman and lady who lived near us, but whom we had never before met, dressed in their every-day clothes—the lady with a light shawl over her head, and her knitting in her hand—I was unaffectedly glad to see them, though an unfinished mattress was spread upon the floor. We all sat down at case, and Paterfamilias ate his "little frugal," and we proceeded to get acquainted in very happy our-folksy fashion. I felt that they had accepted us at once as neighbors, and that they had no particular anxiety about the proper time, or form of their call. This is the right way to treat new neighbors, I thought, and I was sure I should "run in" often to see the new neighbor, following her example and taking my work with me.

Getting Away from Home.

Just twice in three months have I entered the next house to see the good neighbor I like so much. Just twice in the same time have I crossed the street to sit down in the house of another friendly neighbor, whose children play with mine almost daily. And that is the best I have done anywhere in the way of neighborly sociability in the meantime.—I don't like it. I did not mean to do so. I never supposed I should come to this. One might almost as well be living back in the woods out of sight and hearing of neighbors. Whenever I do get out from home I hear other people apologizing and explaining why they have not been to this or that place. Mothers and housekeepers find their time fully occupied, and a habit of keeping close at home is easily formed. It is unsocial. It is unwholesome for the woman who keeps so close at home, and for her family. Contact with the world does us good. To brighten our wits and warm our hearts, is the effect of good, honest sociability.

We get tired of the daily routine of household labor. Sometimes it becomes a weary treadmill, where we are driven almost beyond our ability to keep up with the demand. How good, then, is a little rest, a little change of scene. "All work and no play makes Jack a dull boy." This morning I heard a little girl say, "I shall stay in at recess to-day and study my arithmetic, for to-morrow is examination."—"No," I said. "Study your best in school hours, but run out at recess and have a good play spell, and you can study enough better after such a breathing spell, to more than make up for the extra study at recess."—I find the truth of this when I take a little "outing" myself. I love my family better, and I like my work better after having left them for a little while.

But I am not at all satisfied with the conditions of domestic life, which make it so extremely difficult for neighbors to be neighborly. If I did not believe in the possibility as well as the desirability of other conditions, I would say nothing about it. Personal complaints about hard times are foolish while the whole creation groaneth and travaileth in pain, and no one is exempt. But the grand principle of compensation runs through all, so that human conditions are more equal, thoroughly considered, than it seems to the mere surface observer.

Somewhere to Go.

Last summer, in a small country village, I was talking with a young farmer about the Sunday

evening Temperance Meetings. He said he should be very sorry to have them dropped, because he wanted "somewhere to go." I knew what he meant, for I felt the same want myself, though perhaps not just as he did. I wanted to get out among my neighbors, but I had not time for social visiting. These Temperance Meetings were the nearest approach to social gatherings, open to all, which the little town afforded. No village or hamlet should live in such social poverty. A good lyceum, somewhat social in its character, is an excellent safety-valve as well as educator, among the people of a neighborhood. For lack of this, men and boys loaf about stores and saloons, and women and girls gossip in neighboring houses, or resort to "tea fights,"—a name I have heard given to tea-parties. These are not necessarily sinful or foolish, but they seldom satisfy the demands of real sociability. They are quite out of my line of experience and observation for some years past, but I hear of tea-parties, not a thousand miles from here, where fourteen kinds of cake are served, and a lady who provides only seven kinds of nice expensive cake considers herself quite moderate and economical. Sociables and clubs in neighborhoods and church societies, have become quite common, and often prove very sensible and profitable in their entertainments. These, with lectures and concerts, fill the week for some of my readers, so full of social and intellectual pleasure, that they most feel the lack of quiet evenings at home. The problem is—how to mingle socially with our neighbors without encroaching upon peaceful family life?

What to Eat with Our Bread.

A good deal was said, last summer, about "bread and water" as food for the laboring man. I could not help thinking how few people eat bread that is really good and nourishing, and how difficult it is at present to supply ourselves with pure water. The bread that most people eat, can not alone furnish such nutriment as the body (and mind) require to promote their growth and vigor. Even when our bread contains all the elements of the grain needed for our nourishment, it can not alone satisfy the demands of a healthy appetite. We must have something with it, to afford variety, and to give that contented condition to the stomach so necessary for perfect nutrition. Setting aside meat and butter—for most people will supply themselves with these as they are able—let us think of some simple inexpensive dishes which may make our good bread go down more easily, and set more comfortably than it would alone. I have had this to consider a good deal in working for myself and the children, in their father's absence, where no warm drinks were used, and where meat was seldom at hand.

I will stop right here to say that "in the abstract" I do not believe in "fifteen-cent dinners for the laboring man," and his family, nor in pinched supplies that taste of the coppers they cost for any body. I wish that you and I, and all of us, could go, when we are hungry, to a table bountifully supplied with a great variety of nutritious and delicious kinds of food, perfectly prepared and beautifully arranged. And you should take a bunch of grapes and I a cracker, or I a cup of milk, and you a sandwich, or you a bit of beef steak and I a plate of soup, just as we felt inclined. But for most of us this is simply impossible. Mary, who wrote to me for advice about cheap living, is trying to economize in every reasonable way in order that she and her John may ere long have a home of their own. Some of the rest of us live under the shadow of unpaid taxes, or interest on mortgages most difficult to raise. For all of us, economy is a good thing, but those of us who are poor, are often driven to pinch ourselves. So we will not now say a word about canned fruit, or a supply of the most tempting articles of food to be found in the market. Just here we will only consider what inexpensive dishes we can eat with our bread to make a good meal, besides meat or butter, or milk or tea, or coffee. Among vegetables, first comes the potato. But if simply boiled or baked, it becomes itself

only a part of the back-ground (so to speak) of the meal, and it also needs something—meat, butter, or milk—to go "with it." When warmed over, and seasoned with butter or cream, and salt, it will do for a kind of sauce; also, when mashed, and well seasoned, or when made into potato pudding. Indeed, the potato seems almost indispensable as a part of a warm dinner, for all of the other vegetables relish rather better when a little simple potato goes with them. Sometimes this every-day vegetable must be omitted. Mashed turnips or squash, cabbage chopped and cooked with milk, onions boiled an hour (or thereabouts) with a milk or cream

Fig. 1.—REVOLVING CLOTHES DRYER.

gravy made with them after the water is poured off, or onions sliced and cooked for half an hour or more in a covered frying pan, with a tablespoonful of butter and a little salt, salsify cooked with cream gravy, and parsnips cooked the same, or in other ways—all of these, and other vegetables, go to make up a wholesome variety, using only one or two at the same family meal. But every one of them must be thoroughly cooked, and then not one will sit hard on the stomach, or tend to an undue production of gas. Sweet corn, both fresh and dried, helps well to fill the bill of fare. We must not forget beans, which abound so in nourishment. But they must be very thoroughly cooked. For soup they should be boiled about five hours. Seasoned then with cream, or butter, and with salt, they ought to be relished by everybody. However I may have seasoned this soup, my children always wish to add milk upon their plates. Baked beans must either be boiled until very soft before baking, or must be baked a long time—from three to six hours, if not previously very tender—with a good deal of liquid in the jar, or pan. Those who use pork at all, usually put a piece of fat salt pork in the dish of beans prepared for baking. But some of us very much prefer a seasoning of cream or butter. Split-pea soup, or common unsplit dried peas, boiled five or six hours without meat, is very nutritious, and much liked by many. I season it with salt, and cream or milk if I have it—the more the better—otherwise with butter.

I have said nothing about fruit sauce, but there is a demand for variety in the Topics as well as in our meals, so I will change the subject at present.

A Good Dish for an Invalid,

warranted not to injure the well. Crumb crackers into a bowl—more or less, according to the size of the crackers. Pour boiling water, sufficient to soak them, over the crumbs. Break a fresh egg, and add quickly, stirring the whole rapidly. The boiling water cooks the egg. Season according to discretion, with salt, pepper, cream, or butter.

Some Out-Door Conveniences.

Mr. L. D. Snook, Yates Co., N. Y., who has in former volumes given a number of ingenious and useful in-door contrivances, for facilitating the work of the housekeeper, now sends two, which, though properly belonging to the household, are for out-door purposes. One of these is

A Revolving Clothes-Line.

In towns and villages, where space must be econ-

omized, and where the demands of the garden will not allow of a wide space for the clothes yard, some contrivance for drying clothes within a small area becomes necessary. Various devices, in the way of clothes' driers, have been invented and patented, but they are not essentially superior to the quite old one here given. This is designed for the regular family washing, and is to be set up in a convenient place in the yard. Any one of fair ingenuity can contrive a similar affair, to be used in a spare room in winter, in times when clothes will not dry out of doors. This revolving clothes drier, shown in perspective at figure 1, may be easily made by any one handy with tools in half a day, from the following directions:

A wooden hub, B, fig. 1, 8 to 10 inches in diameter, is mortised with 6 holes, for the reception of the arms, A, A, these are from 5 to 7 feet in length, 7 feet being sufficient to hold the washing for a large family. It will be found less work to simply bore 6 2-inch holes in the hub B, and round the end of arms A. Give the ends of these a good coat of paint, and drive them firmly into the hub. Small holes are bored, from 8 to 10 inches apart, the whole length of the arms, excepting for 15 inches of each arm nearest the hub. The clothes line is to be strung through the holes; and a white wire clothes line is preferable, as it will outlast a dozen hemp or cotton ones. The standard, (fig. 2), is simply a common post set firmly in the ground; in the top of this is driven, as a pin-

 Fig. 2.—POST FOR DRYER.
 tle, a round iron bar, 1½ inch in diameter, and left projecting 6 inches; this of course fits into a hole in the hub. Holes in the hub should be so bored that the outer end of each arm will be from 8 to 12 inches higher than the hub. When hanging out clothes, so soon as one section is filled, revolve the line a few feet, and when that is filled, continue the operation; by this plan there is no traveling from 50 to 100 feet along the line in the snow, wet grass, etc., as by the old method.... Dust and mud are two of the terrors of the neat housekeeper. We have sometimes thought, if a part of the labor devoted to dusting and sweeping, to get these unwelcome guests out, were devoted to prevent them from coming in, the result would be more satisfactory. There is a great difference in men, in respect to "tracking" earth in its various forms into the house; some will always think of, and see to the condition of their feet—or the boots or shoes which cover them—while others, no matter how many scrapers, mats, and other preventives are provided, will forget to use them. Scrapers and mats are provided at each door, but especially in the spring, when the soil is often wet and adhesive, and many persons pass in and out, these are insufficient, and the scrapings accumulate in such quantities, as to make it necessary to remove them frequently. Mr. Snook sends a sketch of

A Portable Scraper and Mat,

an engraving of which is given in fig. 3; this is a moderately heavy board, about 10 inches wide, and 30 to 36 inches long. Near one end is attached a stout scraper, which any blacksmith can hammer out. At the other end of the board, and well out of the way of the scraper, is a coarse mat; this may be of "Coir," or cocoa-nut fiber, such as are sold in the stores, or the domestic husk-mat, but whatever

Fig. 3.—PORTABLE SCRAPER AND MAT.

kind is used, it should be one that will stand hard usage, and well fastened to the board. A very good mat for this use may be made by boring inch-holes at regular intervals in a board, drawing through them tufts of doubled corn-husks, so that

the ends will all be at one side, and then shearing off the ends of the husks, fairly even, but not too smooth. A board thus stuffed with husks, and nailed to the one that holds the scraper, would answer. A scraper and rough mat being provided, as here represented—and there should be several of them—they should not be placed at the house, but where they will be used at some distance from it. Almost every farm-house is surrounded by its garden, or front-yard, and in these the walks are, or should be, in good order. Such a scraper and mat should be placed where the men leave the fields or the barn-yard, and enter the better kept surroundings of the house. If these are placed where they may be used, at some distance from the house, it will prevent much mud from being brought to and accumulating on the piazza and steps, and the "thickest of it" being removed by these, the foot-cleaning contrivances at the house will serve for finishing, and be kept in better condition.

Strong Button Holes.

Mothers who sometimes buy cheap ready-made garments for their families, or who "put out" a part of their sewing, are often annoyed by the weakness of the button holes, which break out on very slight provocation. In making button-holes on drawer bands or aprons, or where they are likely to get torn out, I strengthen them before working the edge, by sewing a long stitch from one end of the slit to the other, on each side, sewing a stitch several times across the end where the strain comes. This is more important than the use of a very coarse thread without these strengthening lines. Tailors have another way of strengthening their button-holes on cloth, but I am not now competent to give their process—exactly. I am only thinking of the little garments to be worn by children who turn summersaults, climb trees and fences, and chase and catch each other. F. R.

Avoidable Misery and Deaths.

Not a cheerful topic, but one that it is our duty to treat. We have hardly looked through a paper for several months, without finding a notice of serious burning or death, from the careless use of kerosene. Did all these casualties occur in one place, and within a few days of one another, the account would be more appalling than that of the yellow fever in a Florida city, or of a battle in Turkey. As they are scattered here and there, but little heed is paid to them—yet the aggregate of kerosene accidents is frightful, and what is the most distressing feature, they are all avoidable. A large share of these accidents—so-called—result from the use of kerosene in kindling fires. Bridget finds the wood is damp, or the kindlings do not burn up at once, so she gets the can, and pours on the kerosene—that is usually the last of Bridget. We do not call these accidents—they are wilful self-slaughter. We suppose there is no help for absolute idiocy of this kind. But this is not the kind of danger to which those who read the *American Agriculturist* are exposed. We assume that those sufficiently intelligent to read, will not try to kindle a fire with gunpowder, or with kerosene. But besides these suicidal performances, we find that there is just now an epidemic of lamp explosions. These, while equally avoidable with the fire-kindling catastrophes, are likely to occur with a different class of persons, and now, as long evenings make the use of lamps more general, it is important for every housekeeper to think of this matter. What kind of kerosene are you using?—It is not well to trust altogether to the storekeeper; it is a matter of quite too much consequence to be indifferent about. There is danger, and great danger, in poor oils; with good oils there is no danger—provided ordinary care be used. The light oils give just as brilliant a light as the heavy ones, they are much cheaper—but you use them at a fearful risk. The names of certain makers, such as Pratt, Devoe, and others, are a guarantee of the safety of their oils—provided they reach the consumer as they left the

factory. Any oil that gives off an inflammable vapor at a heat of less than 110° is unsafe; this is the lowest that should be tolerated, and the best oils will stand the test of 150° or more. It is a matter of vital importance—of life and death—and it is an imperative duty of all housekeepers to see that they are furnished with safe oils. If the person with whom you deal can not furnish them, go to the next town, or elsewhere, until they can be found, and in the mean time use tallow dips, or anything but cheap oils. If nothing better can be done, let two or three neighbors combine and send for a barrel of some reliable brand, but under no circumstances use unsafe oils for a single night. Lamps never explode, the vapor of unsafe oil does, and will, somehow, in spite of every lamp. No matter what the kind of oil, never fill a lamp while it is lighted, and even with the best oil, be as careful as if it were unsafe.

BOYS & GIRLS' COLUMNS.

An In-Door Game with Marbles.

BY L. D. SNOOK, YATES CO., PA.

[Here, youngsters, your friend, Mr. L. D. Snook, comes around again; this time he has a game to be played with marbles in the house—in fact, on a special table, but a table so simple that any boy who can use a saw can make one. I generally try all such things before I give them to you, but I have not had time to try this, and I am very sure that Mr. Snook would not give you anything that was so difficult as to require more than fair skill—though he says that it takes skill and practice to play it well.—THE DOCTOR.]

The game requires a board, which is made from a piece of stuff, 14 inches wide and 18 inches in length at its longest part. A thin wooden strip is nailed around the edge, except at a space of 6 inches at A, where four marbles are placed in small indentations in the board and one inch from the edge. Five strips, K, K, K, K, K, one-quarter of an inch thick and half an inch wide, and from 4 to 9 inches in length, are glued or tacked upon the surface of the board at the angle shown—the spaces between these division strips are numbered from 10 to 50, as shown in the engraving. Besides this, are required a small mallet and a slate for keeping the account of the game. To play the game, each marble is struck in succession by the mallet in such a manner that it will strike the end strip, S, or side strip, T, and rebound at an angle and enter one of the numbered division spaces. Each marble is struck in succession, and all are to remain upon the board until the last one is struck. A marble coming at rest in the division marked 30, is to be counted so many off, or should it be so unfortunate as to stop in the open space marked 5, or the playground marked 20, they also must be counted off—thus the player will find that it is skill and not luck that wins. The dotted lines, M, show the course a marble will take when struck by the mallet. A large number can play at this game, each one having a shot at four marbles, the count of each person, with the discounts, being kept on a slate or piece of paper.

Aunt Sue's Chats.

HORACE.—"The seven wise men of Greece" are supposed to have lived in the fifth century before Christ. Their names are Bias, Thales, Chilo, Pittacus, Solon, Periander, and Cleobulus. The reason of their being called "wise," is given differently by authors, but the most approved accounts state that as some Coans were fishing, some strangers from Melitus brought whatever should be in the nets without seeing it. When the nets were brought in they were found to contain a golden tripod which Helen is supposed to have thrown there. A dispute arose between the fishermen and the strangers with regard to whom it belonged, and, as they could not agree, they took it to the temple of Apollo, and consulted the priestess as to what should be done with it. She said it must be given to the wisest man in Greece; and it was

accordingly sent to Bias, who declared that Thales was wiser, and sent it to him. Thales sent it to another, and so on until it had passed through the hands of all the men distinguished afterwards as the "Seven Wise Men;" and

A GAME TO BE PLAYED WITH MARBLES.

as each one claimed that the other was wiser than he, it was finally sent to the temple of Apollo. I suppose these gentlemen were known to be wise because they, themselves, believed in their own ignorance, and "much wisdom teaches how little mortals know."

RAISING CANARIES.—IRENE B. asks: "Will you please to give some information as to the management and the treatment of canary birds?"—If you want to mate a pair of canaries, let them be side by side in separate cages for some time before you put them together. When you do place them in the same cage, don't be surprised if they quarrel a little at first. As soon as they appear to be acquainted, put some tow and lincn ravelings into the cage, and let them make their own nest. Keep the cage where the birds will not be disturbed. If you find that the eggs,

1. HOME-MADE PHOTOGRAPH FRAME.—See next page.

after being laid, disappear, (the birds often eat them,) take them away one at a time as they are laid, and place them carefully in cotton, giving the bird some imitation eggs in her nest. The nest-eggs may be of chalk, wood, or even of white wax, and are to be kept in the nest until she begins to sit steadily, then remove the sham eggs, and replace the real ones. When the young birds appear, give them, for food, boiled and mashed rape seeds; egg, boiled hard, and bread crumbs, all thoroughly mixed to-

gether. The parents will feed them. I presume there are books on the subject which would give you more elaborate information, but perhaps the above will suffice.

A HOME-MADE FRAME, for imperial photographs, (or other small pictures,) has been contrived by some clever person. It is made of white perforated card-board, and appears as in figure 1, on p. 105. Cut the card about 9½ inches long, by 7 inches wide. Cut out the center 5 in. long by 3 in. wide. Figure 2, which shows a corner of the frame, will give you an idea of how many holes to leave around the different squares. After cutting out the frame, overhand the edges (as shown in fig. 1) with floss-silk, of any color you choose. I prefer brown or maroon. The figures are all worked with the same shade of silk.

Fig. 2.—CORNER OF FRAME.

Of course you can vary the pattern of embroidery to suit your taste, and you can use split zephyr if preferred. When finished, fasten your picture securely to the frame by a few sly stitches of the silk, hidden in the embroidered figures, and sew ribbon, of the same color as the silk, at the upper corners, by which to hang it, as shown in fig. 1.

Jos. H. B.—No one sent me an answer to the "more difficult puzzle." Thanks for your excellent charads.

Thanks for letters, puzzles, etc., to Fanny Bond, Nemo, Bob O'Link, Gus, Ettie Newbury, A. Sinclair, J. Bellis, and others, whose favors I hope to answer at some future time.

Aunt Sue's Puzzle-Box.

[The Microscope crowds the Puzzle Box this time, but we have something quite new and good for next month.]

We have not had any *arithmorem* puzzle in a long time, and as they sharpen the wits both in their construction and in their solution, I propose to introduce them again. They are based upon the Roman numerals, which are represented by letters, and as they are not mentioned in all dictionaries, I will give a list of them here. You all know that M stands for one thousand, D for five hundred, C for one hundred, L for fifty, X for ten, V for five, and I for one, but many of you do not know that A also stands for 500; so I will give you the list alphabetically:

A=500.	G=400.	N=900	T=160.
B=300.	H=200.	O=11 & 0.	V=5.
C=100.	I=1.	P=100.	W=55.
D=500.	K=250.	Q=500.	X=10.
E=250.	L=50.	R=80.	Y=150.
F=40.	M=1000.	S=7.	Z=2000.

All the above letters were used by the Romans, to represent the figures attached, except W, which we have credited with 55, because it is two Vs.

Now let us write the word VEX with the numerals—525010. That is simple enough, but 10 does not always stand for X—e. g., 1000801604005010 ends with 10 and stands for *portfolio*. Then you may put in an 8 to stand for "ate," and 4 for "for," 2 for "to," etc.; thus—429008—"fortunate." With these instructions, I think you will have no difficulty in solving the following simple ARITHMOREMS.

1. 10050090050050250.
2. 100008016050050.
3. 1750500900500.
4. 71100010050250.
5. 50016010500.
6. 100111900160.
7. 1010715250.
8. 100002507.
9. 10015150.
10. 20000100.

DROP LETTER PUZZLE.

Add six letters (in the blanks) and make one word of the following:

— O — N — E — P — — I — — E.

CROSS-WORD.

My first is in treasure but not in gold,
My next is in ancient but not in old,
My third is in beauty but not in fori,
My fourth is in thunder but not in storm,
My fifth is in feature but not in face,
My sixth is in kindred but not in race,
My seventh is in glare but not in sun,
My eighth is in play but not in fun:

The letters you'll discover—
If properly you seek—
That give the name of something
We mention every week.

DIAMOND PUZZLE.

1. The end of a thief. 2. An epoch. 3. A color. 4. Contests. 5. Timorously. 6. A disagreeable trait. 7. Splendid. 8. Foreign. 9. A crevice. 10. A viper. 11. Part of a house.—The center letters, perpendicular and horizontal, name that which is the cause of many an unhappy household.

PI.

Diper si na gravexatant iponino forou now thinrowses:
nativy si na direnation seerid hatt thoser hudlos hares
ahht onlompi.

ANSWERS TO PUZZLES IN THE JANUARY NUMBER.

PI.—The soul that suffers is stronger than the soul that rejoices.

ADDITION OF FRACTION.—Take the necessary letters from the words (1) attire, (2) bayberry, (3) communicate, (4) confascatory, (5) likely, and (6) illustrate, and make "Try your skill."

NUMERICAL ENIGMAS.—1. For wisdom is better than rubies; and all the things that may be desired are not to be compared to it. 2. Bacchus is the god of wine and Venus is the goddess of love. 3. Grindstone. 4. Androscoggin.

ALPHABETICAL ARITHMETIC.—Key—"Golden Harp."

CONUNDRUM.—It became a statuette (statue—wet).

CROSS-WORD.—Washington.

TRANSPPOSITIONS.—Name, mean, mane, amen.

HIDDEN RIVERS.—1. Po. 2. Thames. 3. Obe. 4. Red. 5. Ohio. 6. Pearl.

Send communications intended for Aunt Sue, to Box 111, P. O., Brooklyn, N. Y., and not to 245 Broadway.

Our Young Microscopists' Club.

Well! "The Doctor" is now fairly set up in business! Here is a lot of letters all about microscopic matters. I wish there were ten times as many, for if you think you are all to learn something from me, and I get nothing in return, you are mistaken. Every letter from boy or girl, that tells me of some difficulty, or asks me a question, is very likely to teach me something, and though they call me an "old man," I am not yet too old to learn. So come on with your letters. But first I will attend to those letters that relate to

THE MICROSCOPE ITSELF.

In sending this instrument to tens of thousands, and I should not be surprised to know that, by the time you get this, a hundred thousand had been sent out, it will go into many hands that had never seen anything of the kind before, have no idea of its uses, and how to use it. At the request of the Publishers I wrote the circular or description that goes with each Microscope, and in that stated that "patience" was needed on the part of those who should get it. Now let me give you all one bit of advice. In all the thousands who have had the Microscope, a few—and, considering the number, a very few—as it is only 3 or 5, in the whole, found that they could not see anything with it. On examining into the matter, we found they had not read the directions and that

THE TROUBLE WAS WITH THE DIAPHRAGM.

You know that there are three lenses or glasses, one above another, each a stronger magnifier than the one above it. Between the second and the third, or lowest glass, is what is called a *diaphragm*, i. e., a piece of the same material in which the glasses are mounted—hard

rubber—with a small hole through it. When you first get the Microscope, turn this to one side, and learn the use of the glasses *without this*. It is very useful when you are examining the very smallest objects, but at first it bothers persons who have not yet learned the use of it, which is to make the field smaller, and allow you to see more distinctly very small things. At first you should try the upper or weakest glass, and then the others as advised in that circular. After a while, when the Microscope is as familiar to you as your scissors or jack-knife, you will then get the hang of it, and find the diaphragm very useful. Now here is another matter to be considered. You must know that whether in

A MICROSCOPE OR A TELESCOPE,

the important part is the glasses. We could have sent at a cost of \$3, or \$5, a microscope with several mechanical features which this has not, but the object was to send, at a low cost, a useful instrument that every one could afford. I have been, from a boy, in the way of using microscopes of various kinds, and I know that I could not get a *single good glass* at the price at which this, with *three glasses* mounted on a stand, comes to you. In the sheet of description that goes with the Microscope, there is pointed out a fault.—That is,

THE UPRIGHT OR WIRE STANDARD

on which the glasses slide, is in the way. This was seen at first, but to remedy it in the making, we should be obliged to about *double the cost*, and this we chose to avoid, preferring to give the Microscope at a low price, and point out this difficulty—which can be easily avoided by care. I had thought of a plan of overcoming this trouble of having the wire standard always in the way, but a correspondent at Springfield, Mass., "Mr. O'Ray," sends us a better one, and one which any person with a little ingenuity can adopt. Indeed, having these glasses—which, after all, are the important and the costly part—you can make various improvements, as I shall show from time to time. This improvement, which I will call

AN EYE PIECE FOR THE MICROSCOPE,

can be made by any one who has the least ingenuity. The materials needed are: a piece of brown paper, paste, a bottle cork, and some ink. The tools are: scissors, a sharp pen-knife, a piece of strong thread, an awl, and a stick. In the first place whittle your stick smooth, half an inch through. Cut your brown paper, according to its thickness, into a strip one inch wide and 18 inches or two feet long. You wish to make a tube of this paper, so you will paste it well—good stiff flour paste is best, but mangle or gum will answer—and wind it round and evenly on your stick. It should be about 1/16 of an inch thick, and when thoroughly dry, you will find it very stiff

2.—CORK. 1.—TUBE. 3.—EYE PIECE. Figure 1 shows this tube. To mount it, cut from your bottle cork a slice about half an inch thick, and shape it to fit your paper tube, as in figure 2. Our friend "O'Ray" uses a piece of wood, but I think cork is better. Make a hole with an awl, to allow it to go upon the wire standard of your Microscope, paste (or gum) the concave surface, and put it on your paper tube, as in figure 3, tie it fast with the piece of thread, and let it dry. Now try it on the Microscope, as in figure 4, and if an inch, as here directed, is too long, cut it down by the use of a sharp knife, until the things you have seen without it appear as plain as with it. Most eyes will be suited at an inch from the glass. Having it all right, then blacken the whole with ink, and if you have no brush to use for the purpose—recollect that young microscopists must learn to use make-shifts; wind a bit of small twine, or strip of rag, on the end of a match, or other stick, and use this swab to paint it inside and out. If after drying it is not black enough, swab the ink over it again. Boys and girls, let's give Mr. O'Ray our thanks....Here is another matter

Fig. 4. MICROSCOPE WITH EYE-PIECE.

ABOUT THE MICROSCOPE

that I am sure will interest a great many of you. You saw in the paper that goes with the Microscope, that I told you how to mount it, for convenient working, upon a cigar-box. Now comes Mr. R. M. Bailey, of Middlebury, Vt.—who is editor of the "Middlebury Register," and who knows all about microscopes, has a very powerful one, and who finds the *American Agriculturist* Microscope of great use in preparing objects for his fine costly instrument—who tells us something that many of you will like to know and copy. You know that with our Microscope as it is, you must, to see *transparent* objects, hold it up to the light. Mr. B. mounts his microscope upon a cigar-box as there advised (fig. 5), but just under where

the glass stage of the microscope comes, he bores an inch hole (D). Then in the cigar-box, he places, as

Fig. 5.—MR. BAILEY'S CONTRIVANCE.

you see in figure 5, a mirror (B), so arranged that it can be turned to any angle, to reflect the light,

WHETHER DAY-LIGHT OR LAMP-LIGHT,

up through the hole in the cigar-box, and through the glass stage of the microscope, and thus allowing all transparent objects to be seen as the microscope stands, without holding it up to the light. You see how he has done it.—He turned a round stick, left a piece to hold the mirror, and worked that

Fig. 6.—BOARD FOR MOUNTING MIRROR.

out afterwards with chisels. He put a standard upright (A) in the box; one end of his piece which holds the mirror goes into a hole in this standard, the other (C) through a hole in one end of the box. But you who have no turning lathe must have something simple. Whittle a round stick that will go quite through the cigar-box, and project half an inch at each end. Make a flat place on the middle of the stick; upon this tack, or with small nails, attach a thin piece of stuff, such as the cigar-box is made of, as in figure 6. Get your mirror; any piece of looking-glass will do, and if you can't get it cut to just the shape you would like, never mind.

Fig. 7.—MIRROR MOUNTED.

Fasten your piece of looking-glass to the board on the round stick by means of strips of paper and paste, if cut square, as in figure 6, but if you can't cut it, fasten it on somehow by bands and strips, as in figure. All you want is a piece of looking-glass that will throw light up through the hole in your cigar-box, that will allow you to see transparent objects with the Microscope as it stands there. Figure 5 shows Mr. B.'s neat arrangement, figs. 6 and 7 show how to fix a regular bit of looking-glass, if you can get one, and figure 8 hints at an irregular bit. Only recollect that you wish to put a reflector at any desired angle, and keep it there, and you will do it somehow. Remember it is not those who have the most costly instruments that learn the most, and one great use of

Fig. 8.—ROUGH MIRROR.

the *American Agriculturist* Microscope will be to put you up to contriving things. You know that those in any peculiar occupation have their own terms; so, Microscopists talk about things which others will not understand. They will talk about "preparations," "slides," and "mounted slides." You look at something which interests you, no matter what it may be—a small seed or a minute insect, or the part of one, and you wish to prepare this so that you can look at it again—and in this you will find much of interest in the Microscope—you would like to put it in some shape that will allow you to show it to some one else, it may be to-day, but more likely days, or weeks, from now. Anything put up or prepared to be kept and examined at some future time

IS CALLED A PREPARATION OR MOUNTED OBJECT.

It may be some simple thing, or it may be some dissection or part of an insect, that you have spent hours upon. Now I come to this matter of "preparations," knowing that there are many difficulties, but I will try to make it as plain as possible; besides this, it is a matter on which considerable money may be expended, and I must keep that in view too. In fact, those who will wish to go to much expense, will have a more costly microscope than

ours of the *American Agriculturist*, and will be able to get some of the many books on the subject.... So to begin with the simplest kind of preparation. But in the first place, let me tell you that my microscope talk has run over into the old-folks' part of the paper, and you will find on page 103 a talk about clover seeds, and the seeds of weeds that may be mixed with the clover, which you may care to look at, especially as on the circular that goes with each Microscope, something is said about clover seeds. But

TO GET BACK TO OUR PREPARATION.

You have seen the seed of Red Clover, and of White Clover, under your Microscope, and you would like to be able to tell one from another, and these from any other clover or any other seeds. You might keep a little sample of each done up in a paper, or what would be neater, in a little pill-box, which, as apothecaries have but little use for the very smallest size, you might be able to get very cheap from your apothecary. But in either case, you would have to get at your seeds, open the box, to put the seeds on the stage, and it would be a long job and a great deal of trouble. How much better it would be to have the seeds that you might wish to look at again

ALREADY MOUNTED.

Now to begin with, about mounting, as preparing objects, (meaning anything to be looked at,) let us start with some clover seeds. We have called the squares of glass (made square because they take up less room and weigh less, but would be more convenient if twice as long as wide) slides. We start with clover, or such like seeds, and you will recollect that these are to be looked at as opaque objects—i. e., the light falls upon, but does not shine through them. So you will see from the start that the slide for these need not be of glass. The best material for this purpose will be wood. Use a thin piece—a very thin piece of wood—your cigar-box wood—a piece of stiff veneer—anything that is thin, and not clumsy. It is well to start with a size, and as microscopists have, for their powerful instruments, found that one by three inches is a convenient size, we may as well have ours of that size. So get out some wooden slips 3 inches long and 1 inch wide, and of any wood you choose, worked thin. I say "some," because it is well always to have a lot on hand, to mount other seeds that may come along. Having your wooden slides ready, you will then want

SOME PASTE-BOARD SLIDES

of just the same size. Any stiff card-board will do; old boxes may be put to good use, and you will want—recollect that we are to use them for seeds—slides of different thicknesses. Well, having your paste-boards of the size of your wooden slides, you will need to make a hole in the paste-boards. This hole may be $\frac{1}{2}$ an inch across, or of that of the size of the "cell" which comes with the Microscope. Now about cutting these holes: If you have a brother, or a neighbor who uses a gun and has a "patch cutter,"—which is a sharp steel ring, that with a blow, will cut a neat circle out of your paste-board slides—you can borrow that. If not, use the cell, mark through it on

Fig. 9.—WOODEN SLIDE.

your paste-board slide with a pencil, and then cut the hole with a sharp pen-knife. If there is a rough edge, rub it down with something smooth. Having your wooden slide (fig. 9) and your paste-board slide with the hole through it, (fig. 10), then stick them together, with flour paste or mucilage, and put them under a weight—so that the paste board will not curl, until dry. But we are not through yet. We must blacken the slide. As directed for making the eye-piece, use black ink, and blacken the cavity in your slide. Now it will be a very shallow cell, with a wooden bottom and paste-board all around.

Fig. 10.—PASTE-BOARD CELL.

Blacken the whole of this cavity well, and if one coat of ink is not enough, put on another. Having done this, now for your seeds, and this will require some care. Select half a dozen or so of the seeds that you wish to keep, touch the least quantity of mucilage, to the spot, and then put on your seeds, one at a time. Here you will find the little forceps, mentioned in the circular, come into good service, but with care, and a small knife, you can manage without those. Let the mucilage holding the seeds in place in the cavity of your slide dry. You then will want to finish the mounting. Take a piece of any rather stout paper, white or any color you choose, of the right size, to quite cover your slide; make a hole in this, to correspond with the hole in the paste-board. Cover the wrong side with paste, or mucilage, putting it on neatly, and let it dry. You will now have a strip of wood, a strip of paste-board with a hole in it, forming a cell, in which

Fig. 11.—THE SLIDE COMPLETE.

are your seeds, and all bound together by a strip of paper. Now on the paper you will write the name of your specimen. We will suppose it to be "Red Clover." Write this neatly on one side of the cell, and if you choose you can put a number on the other, (fig. 11). It will take less time to do this, than I have taken to write it, and you have a slide that you can refer to at any time, if you wish to know how red clover looks. In a similar manner you can put up seeds of all the clover weeds which are described in the article on page 103.

When you hear the frogs peep, and the toads sing their spring song, (for toads do sing after their way), it will re-

Fig. 12.—FROG-SPAWN. Fig. 13. EGGS. Fig. 14.

mind you to look after their spawn. No doubt that those of you who live in the country know what it is—a mass of very clear jelly, which you can find in almost every pool of water in early spring. This is sometimes called "frogs-spittle," but it is really the spawn of either frogs or toads. Get some of the spawn—you will not want much, a table-spoonful or so will do—place it in a saucer of water. It is a mass of eggs, held together by a clear jelly-like matter. Look at it with the Microscope, and you will see

Fig. 15. Fig. 16.—VERY YOUNG TADPOLE.

spots all through it, as in fig. 12. These are the yolks of the eggs, and the interesting portion of the spawn. Keep the saucer in a warm room, near the window, and add water as it evaporates. You will need to look at it every day with your Microscope, taking off a bit and placing it on the slide. You will first notice that the yolk changes its shape, and begins to divide, first as in figure 13, then as in figure 14. The spots also increase in size, so that after a while you can see, without the glass, the form of the young animal, as in figure 15. Soon the eyes appear, figure 16, then a little hole shows where the mouth will be. All this while the animal has been growing, and as it has had no mouth, you are quite sure that it has eaten nothing. All the material for its growth has come from the jelly around it, but now having a mouth, and being able to live in another way, it wriggles about and gets away from the jelly, and swims freely in the water as a

TADPOLE, OR POLLYWOG,

as it is often called. Figure 17 shows the Tadpole as we

Fig. 17.—DEVELOPED TADPOLE.

generally see it, but if you carefully examine the animal when very young, you will find some curious fringe-like things on each side of the head, as in figure 18. Those are the gills with which the young animal breathes at first, but it soon loses these, as I shall tell you another time. If in going about you find in the pools fresh water snails, take a few home and put them in a jar or dish of water, and you will no doubt soon find little masses of jelly sticking to the sides of the jar. These little lumps, which are not so large as a pea, contain the

Fig. 18.

EGGS OF THE SNAILS,

surrounded by a jelly in a similar manner to those in the frog-spawn. Their changes and the growth of the snails may be watched from day to day, as advised for the others.

As spring advances, you will find new objects on every hand. A pool, or small pond, will furnish many interesting things, of which I shall say more another time.... Keep a look-out for the eggs of insects, some of which are very beautiful.... As the days get warmer, various small insects will be plenty, and you will find the various plant lice worth studying.... If you find upon a twig, or on a stem of grass, as you no doubt will later, what looks like froth, or spittle, take it home and examine it, and you will find it hides an insect.... When the "tags" appear on the alders and hazels, pick them apart, and see that each scale is really a little very simple flower.... I do not think we shall be obliged to give so much space to contrivances again, and we can give all the more to the objects to be looked for.

THE DOCTOR.

The remarkable adventures of Simon Simpson, Esq. His early education had been neglected, he had never skated when he was young, but when he saw people skating on the pond last winter, it seemed so easy, that he determined to try it this year. He bought his skates, and waited all through December and January, at last there was skating in February, and Mr. Simpson started for the pond. How he succeeded in learning to skate, the engravings given below plainly show.

1.—Mr. Simpson starts for the pond. If he lived in New York, of course it was the pond at Central Park.

2.—Mr. S., not having put on skates before, found a quite corner, where he would not be observed.

3.—Having, after much trouble, fitted his skates, he tries to stand, but finds it more difficult than he expected.

4.—But after several trials he is able to keep his feet, and he goes ahead on his skates. He enjoys skating, but soon

5.—He has a fall. He is not so young and active as he was 20 years ago, and finds getting up difficult.

6.—Shows one of his attempts to get upon his feet, but he was not very successful, and soon after was as in

7.—Which shows the results of his efforts to get up. He finally thinks skating is not such fun as he thought.

8.—He strives hard to get upon his skates, and assume an erect position—with what result is shown in

9.—Poor Mr. Simpson. Having only treacherous skates to stand upon, what can he do but in

10.—to consider the matter. What can be done? As he is, he can not move, but at last help comes in the form of

11.—A small boy, who takes the troublesome skates off of his feet, and Mr. S. started from the pond, as in

12.—Singing "There is no place like Home."—Moral: Don't put off learning to skate until too late.

Special Notice.

To the readers of the American Agriculturist.

There has been such a quantity of utterly worthless, so-called "silver" goods, palmed off on the unsuspecting public during the past year or two, that it seems almost useless to try to educate the people up to a high standard, or ask them to believe an advertised statement. The business has been so demoralized by unscrupulous manufacturers, who have, in their competition, so cheapened the quality of plated ware that it is the worst possible economy to buy it, unless made by some well-known and honorable manufacturer.

Our goods **WE KNOW** are well and **HONESTLY MADE**, and are guaranteed to be just as represented, or the money will be refunded on the return of the goods. The fact that the publishers of this first-class paper will accept our advertisement, together with the liberal notices from other first-class papers, and the kind words of the large numbers who send second and third large orders, is sufficient to place us in the entire confidence of every one. We have first quality metals, beauty of style and unequalled finish, in all our wares: therefore we feel confident of giving satisfaction in each and every case. The prices given covers the cost of the goods, as well as postage and packing. The solid spoons are the regular 4 oz. spoon.

New England Silver Plate Co.,

Feb. 15, 1878.

New Haven, Conn.

Kind Words from Customers.

Mrs. Gilbert, of Coventry, Ct., (as well as many others,) write: "The Solid Tea Spoons received, and am very much pleased with them. Please find \$2 for one set knives."

Miss Ellen Whiting, of Franklinton, N. Y.: "Enclosed find \$2 for set of knives. The forks I am well pleased with."

Hundreds of similar testimonials could be given.

BUSH & SON & MEISSNER,
BUSHBERG, Jefferson Co., Mo.

\$250 in Premiums.

Pringle's New Hybrid Spring Wheats.

CHAMPLAIN.—A bearded variety—a cross between the Black Sea and Golden Drop—combining the remarkable hardness of the former, with the superior quality of the latter. Its strong and vigorous straw, growing 6 to 12 inches higher than its parent varieties, stands erect, frequently bearing even in very ordinary culture heads from 5 to 6 inches in length, containing from 60 to 75 kernels each.
Price, \$1.00 per lb.; 3 lbs. \$2.50, by mail, post-paid.

DEFIANCE.—Another variety of Spring Wheat of the highest promise, the result of a series of experiments, to incorporate superior qualities upon the hardy stock of our common Club Wheat, by hybridizing it with one of the finest, whitest, and most extensively grown sorts of the Pacific Coast.

This variety displays great productiveness, vigor, and hardness. It is a beardless, white chaff wheat, with heads frequently 5 to 6 inches long, very closely set with large white kernels, frequently numbering 75 to 80 to the single head.
Price, \$1 per lb.; 3 lbs. \$2.50, by mail, post-paid.

In order to induce Wheat Growers to give these new sorts a thorough and universal trial, we offer **\$250 in premiums** for the largest quantities grown from 1 pound of seed, also for the 20 largest heads. For particulars see Circular.

Two New Varieties of Potatoes.

BLISS' TRIUMPH.—An extra early variety, ripening a week to ten days earlier than the Early Rose—and one of the most attractive in appearance. Superior quality and very productive.

TRIUMPH.—A new and exceedingly fine, medium early, red-skinned variety, resembling the Snowflake in appearance and quality. It might with propriety be called a Red-Skin Snowflake.

This variety was exhibited in London at the great International Potato Show, in October last, and received a first-class certificate.

Price of each, \$1 per lb.; three lbs. to one address, \$2.50, by mail, post-paid. See Potato Catalogue.

A NEW EARLY PEA.

BLISS' AMERICAN WONDER.—A cross between the Champion of England and Little Gem—combining the good qualities of both varieties, but is earlier and more productive.

½ Pint packages, 25 cts; Pint, 75 cts., by mail, post-paid.

EARLIEST TOMATOES KNOWN.

BLISS' LITTLE GEM.—Numerous testimonials received from those who tested this variety the past season, pronounce it two to three weeks earlier than any other variety. At the great Tomato Trial in London, at the Horticultural Society's gardens, it was the earliest of 60 varieties on trial, and received a first-class certificate. 15 cts. per pkt.

ACME.—This new and beautiful variety is one of the finest ever produced. Its rosy-purple, glossy skin, fine symmetrical form, and delicious flavor, render it worthy of general cultivation. It is also a very early variety, surpassing all others in this respect, excepting the "Little Gem." 15 cts. per pkt.; ¼ ounce pkts. 75 cts.

EARLY LIMA BEAN.—A careful trial of this variety the past season proved it to be ten days earlier than the ordinary variety. 25 cts. per packet.

See our advertisement in February No. of *Agriculturist*.

The New York Weekly Witness says: The New England Silver Plate Co., of New Haven, Ct., are reliable, and make a very attractive offer.

The Illustrated Christian Weekly, published by the American Tract Society, New York, says: The New England Silver Plate Co., of New Haven, Ct., are no humbugs, but will do just as they represent.

The New York Weekly Sun says: The New England Silver Plate Co., of New Haven, furnish first-class articles at a very low price.

Do not confound these first-class goods with the ordinary cheap qualities. They are guaranteed to be exactly as represented, or the money will be refunded.

Silver Plated Table Bells, 80 cts. Napkin Rings from 40 cts. to \$1.75 each.

SOLID SILVER TEA SPOONS, AT MANUFACTURER'S COST PRICES,

is what we can supply the readers of this paper, if desired, at a price as low as any jeweler pays for them at wholesale. We will mail on receipt of price, one set of six **SOLID Silver Tea Spoons** for \$3.50, (cost at retail from \$6 to \$7), or, for 85 cents which covers the cost of the spoons, as well as postage and packing, we will send by mail or express, prepaid.

ONE SET OF 6 QUADRUPLE TEA SPOONS IN CASE, finely and heavily plated with **PURE NICKEL and COIN SILVER**, on a new metal, called **Alfenide**, which is very similar to the finest English white steel. It contains no brass or German silver in its composition, and consequently no poison, or disagreeable taste. Are very strong and will wear for years. Two sets, \$1.50. We shall not furnish these goods to the trade, consequently they cannot be supplied by any other manufacturer or dealer. We also make of same quality, Table Spoons 6 for \$1.75; Forks, 6 for \$1.15; Table Knives, balanced, solid steel handle and blade, triple plate, 6 for \$2. New England Silver Plate Co., Man'rs. New Haven, Ct.

Copyrighted, New England Silver Plate Co., 1877.

H. W. JOHNS ASBESTOS Liquid Paints.

These Paints are in every respect strictly first class, and second to no others in the market in purity, richness, and permanency of color, beauty of finish, and durability. They are prepared ready for the brush, in twelve newest shades, and standard colors, suitable for the tasteful decoration of all classes of buildings, inside and out, and for all purposes where a perfect protective coating is required.

They contain no water, alkali, or other useless or deleterious ingredients, such as are used in nearly all the liquid or so-called chemical paints, and are guaranteed to be the most durable paints in the world for exposed wood and iron work.

Owing to the wonderful covering properties of these Paints, the farmer, merchant, and manufacturer can, by their use, preserve and beautify their buildings, fences, or other wood and iron work, at from one-half to two-thirds of the usual cost of other ready mixed paints, or white lead and linseed oil. These Paints are sold by standard U. S. gallon measure, and our packages contain from one to twelve PER CENT MORE PAINT than those usually sold.

ASBESTOS ROOF PAINT, for tin and shingle roofs, iron-work, agricultural implements, fences, out-buildings, etc. We guarantee this to be a better article than has ever before been offered to the public for similar purposes.

H. W. JOHNS MANUFACTURING CO., 87 Maiden Lane, New York,

MANUFACTURERS OF

Asbestos Roofing, Steam Pipe and Boiler Coverings, Steam Packing, Sheathing, Fire, Acid, and Water-proof Coatings, Cements, etc. Send for Samples, Illustrated Catalogue, Price-Lists, &c.

La Dows Jointed Pulverizing & Smoothing DISC HARROW.

Being jointed in the center, is adapted to both smooth and uneven surfaces. Acknowledged the best of the kind, and will pulverize and cover seed better in one operation, than going over twice with others. Made with both Chilled Metal and Cast Steel Discs polished. Send for circular and price list. Manufactured by WHEELER & MELICK CO., ALBANY, N. Y.

Sugar Maple.

Seedlings by mail, post-paid, 50 cts. per 100, \$3 per 1,000, 6 to 8 inches high. Descriptive and priced catalogue of Forest Trees, with directions for planting, mailed free to all who apply.

W. W. JOHNSON, Central Lake, Autum Co., Mich.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from p. 89.

Quality and Value of Milk.—"T. L. B., Amelia, C. H., Va. On an average, common farm milk will yield about 10 per cent of cream. Milk of this kind sells at the creameries for about 2 1/4 cents per quart, or one cent per pound. A quart of milk weighs 2 2/10 lbs.

When Is a Pig Thoroughbred?—"O. E., Amboy, N. J. Six crosses of pure stock are considered as entitling an animal to be classed as thoroughbred. This gives the animal sixty-three sixty-fourths (63/64) of pure blood. When pigs are carefully bred from well selected boars to this point, and well raised, the breeder may consider his stock as thoroughbred.

The Best Wagon Factory.—"J. W., Talladega, Ala. There are several first-class wagon manufacturers. Among others, the Studebaker Bros. Mfg. Co., of South Bend, Ind.; Semple, Birge & Co., of St. Louis, and the Mitchell Lewis Co., of Racine, Wis.

Book on Swine.—"J. W., Talladega, Ala. Coburn's Swine Husbandry is one of the best books on this subject for all practical purposes. Sent for \$1.75, post-paid, by the Orange Judd Company, New York.

Lice on Pigs.—"W. H. G., Stark Co., Ill. Pigs are very subject to lice. The remedy is a very simple one. Make a mixture of equal parts of lard, or olive oil, and kerosene, and rub this on the parts where the lice are gathered; upon the ridge of the back, beneath the arms and thighs, and about the brisket. At the same time give each pig a teaspoonful of sulphur in its feed, every day, for a week or two.

The Southern Cow Pea.—"H. L., Oakland Co., Mich. The Southern cow pea will not ripen its seed in Michigan, but it can be grown for a fodder crop, or for a green manuring crop, to be plowed in. Seed can be procured from A. E. Blunt, Agricultural Station, McMinn Co., East Tenn., and R. H. Allen & Co., N.Y. City.

Swelling on the Leg of a Cow.—"C. C. P., Rock Hill, Ks. A tumor upon the upper part of the leg of a cow may arise from a blow, a bruise, or possibly from a bite by a snake. Such a tumor would swell, suppurate, break, discharge, and heal without any further trouble. The best treatment of such a swelling is to foment it two or three times a day with warm water until it breaks, and after that, to wash it with warm water and soap, and keep the surrounding skin clean. A tumor which arises from scrofula is practically incurable.

Remedy for the Hessian Fly.—"S. G. H., Fredericksburg, Va., says that farmers in that district use 2 bushels per acre of air-slacked lime as a remedy for the fly. The lime should be sown broadcast over the young wheat when it is wet with dew, it is said to be carried down to the eggs, or larvae, and destroys them. As a protection to the face and hands, they should be well greased while the lime is being sowed.

Death of Flora Temple.—Flora Temple, the first of the really great trotting horses of America, died of old age on the 21st December, 1877, aged 33 years. At the time of her death, she was owned by Mr. Aristides Welch, of Philadelphia. She leaves three descendants, a mare owned by A. B. Conger, of New York; a horse owned by Robert Bonner, of New York City, and another horse owned by Robert Steel, of Philadelphia. Her last colt was foaled in 1871, when she was 27 years old.

Farming in the South.—"D. W. P., New York. There are abundant openings in the South for farmers. Corn, oats, wheat, grass, roots, fodder crops of many kinds that cannot be grown in the Northern States, potatoes, sweet potatoes, sorghum, cotton, and several other staple products can be grown there in perfection. But the greatest of all these is grass, and when it is considered that there are green fields, or green fodder, to be had throughout the winter, any enterprising farmer who would locate in a district where grass grows luxuriantly as in East Tennessee, Western North Carolina, and Northern Georgia, could hardly fail to find a promising opening for his labor and skill, and these present one great advantage over any Northern or Western State, in allowing him the whole year for profitable work.

Fine Hardy Perennial Flowers.

To enjoy flowers with the least trouble, procure and plant those which, when

ONCE PLANTED, WILL BLOOM FOR YEARS.

No trouble with seed-sowing—with hot-beds, or green-houses. The plants will soon form clumps large enough to divide. They are

EVERYBODY'S FLOWERS.

We have by far the largest collection of these plants in the country, including everything from the old-fashioned Bee Balm and Moss Pink, to the latest introductions from all parts of the world. Our Catalogue for 1878, containing the latest additions, and giving much useful information about these popular plants, sent by mail.

My Annual Catalogue of Vegetable and Flower Seed for 1878 will be ready by January, and sent free to all who apply; Customers of last season need not write for it. I offer one of the largest collections of vegetable seed ever sent out by any seed-house in America, a large portion of which were grown on my six seed farms. **Printed Directions for cultivation on every parcel.** All seed sold from my establishment warranted to be both fresh and true to name; so far that should it prove otherwise, I will refill the order gratis. As the original introducer of the Hubbard and Marblehead Squashes, the Marblehead Cabbages, and a score of other new vegetables, I invite the patronage of all who are anxious to have their seed fresh, true, and of the very best strain. **NEW VEGETABLES A SPECIALTY.**

JAMES J. H. GREGORY, Marblehead, Mass.

AMARYLLIS JOHNSONII.

The finest of all; a rich dark crimson, striped pure white, fragrant and of easiest culture. Strong bulbs, \$1 each, post paid. Catalogue of new Verbenas, Petunias, Roses, Dahlias, &c., on application. **DEXTER SNOW,** Chicopee, Mass.

Agents Wanted.

White Prolifer Field Corn.—Produced last year on one acre, 13,226 lbs. of ears, and three to five ears on every stalk. 250 acres of seed farms under my control. Send for illustrated catalogue.

Moreton Farm Seeds.

Harris' American Yellow Globe Mangel Wurzel.—I have grown my own Mangel Wurzel seed for several years, selecting a few of the very best and choicest bulbs annually, from many thousand bushels. It is seed such as is rarely offered for sale. I can confidently recommend it. Price, 4 oz., 20 cents; one lb. 75 cts.; 1½ lbs., \$1.00; 4 lbs. \$2.50. Sent, pre-paid, by mail 10 lbs., or over, by express, at 50 cents per pound.

Blood Turnip Beet.—Same price as above.

Yellow Danvers Onion Seed.—I have grown this variety of onions for fifteen years. The seed I offer was grown by myself in 1877, from very carefully selected bulbs. I can confidently recommend it. Price, 4 oz. 40 cts.; 12 oz. \$1.00; 4 lbs. for \$5.00. Sent pre-paid by mail.

Whethersfield Red Onion Seed.—\$1.00 per pound.
Early Jersey Wakefield Cabbage Seed.—One ounce 80 cents; 4 ounces \$1.00.

Stone Mason Cabbage Seed.—Oz. 25c.; 5 oz. \$1.00.
Six-Rowed Barley.—One dollar per bushel. Bags 10 cents per bushel extra. 20 bushels, or more, including bags, \$1.05 per bushel.

Seed Potatoes.—Early Vermont, Snowflake, Brownell's Beauty, Compton's Surprise, Genesee Co. King, White Peachblows, and Thorburn's genuine Late Rose, \$5.00 per barrel. My stock of Late Rose was obtained direct from Mr. Coy, the originator of this valuable variety. It will, on good land, yield double the crop per acre of Early Rose. Wholesale price on application. NEW!

White Egg Turnip

It is a beauty and is the very choicest variety ever introduced!

"Feed the plant and the plant will feed you."

STOCKBRIDGE MANURES.

Originated by Prof. Stockbridge, Prof. of Agriculture in the MASS. AGRICULTURAL COLLEGE.

These Manures are made for each crop, furnishing the plant food which each particular crop requires. They have produced from

	per Acre,
50 to 80 Bushels Corn	" "
25 to 50 " Wheat	" "
25 to 50 " Oats	" "
150 to 250 " Potatoes	" "
2 to 3 Tons Hay	" "

and other crops in proportion. They have been used the past five years with such success that in 1877 they were applied on 10,000 acres with excellent results.

Send for Pamphlet for 1878, Mailed Free.

BOWKER'S HILL AND DRILL PHOSPHATE,

A very fine, dry, and high grade Phosphate. Also Agricultural Chemicals.

W. H. BOWKER & CO.,

43 Chatham Street . . . Boston.
3 Park Place . . . New York.

THE BEST FERTILIZERS.

Per ton as follows:
GENUINE No. 1 PERUVIAN GUANO, \$56.
Russell Co's Super Phosphate of Lime, \$40.
Double Refined Pondrette, \$22.50.
Ammoniated Animal Matter (Bone, Meat, and Blood), unequaled for this price, \$22.50.
Ground Bone, \$27 & \$30.
Best Land Plaster, \$5 per ton, in barrels.
Send for TWENTY-THIRD annual pamphlet. Order direct of

H. B. GRIFFING,
Dealer in Agricultural Implements and Fertilizers.
60 Courtlandt Street, New York.

Matfield Fertilizer.

This is the only fertilizer professedly containing all the soil elements found in each crop. Prof. W. O. Atwater of the Connecticut Agricultural Station, analyzed six of our different fertilizers, and found in every case, as we guaranteed, that they contained a larger percentage of plant-food elements than we claimed by the labels placed on each package. Send for circular. Address

F. COPELAND,
Treasurer and General Agent Matfield Fertilizer Co.,
13 Doane St., Boston, Mass.

Soluble Pacific Guano.

The Superior excellence of this Guano has been so successfully demonstrated during the past ten years in the Middle and Southern States, on cotton, corn, tobacco, sugar-cane, and garden vegetables—the Company's sales having exceeded the enormous aggregate of 35,000 tons in a single season—that it is now offered for sale with entire confidence as to its merits. No fertilizer ever introduced in this country, has undergone severer tests, or come out of them with its character as a first-class, reliable fertilizer more thoroughly established. In consequence of the satisfactory results of these very complete tests, this Guano has acquired a reputation equal to that formerly enjoyed by Peruvian Guano. It is rich in **Bone Phosphate of Lime**, finely ground (a large proportion of which is immediately soluble), **Ammonia**, and **Potash**, besides other ingredients valuable as plant-food, manufactured at the Company's works, Woods Hole, Mass., and Charleston, S. C., under the supervision of competent chemists.

PACIFIC GUANO CO., BOSTON.

Bone Meal.

Fine ground. Warranted pure. Manufactured by **S. H. MORGAN,** Toledo, Ohio.
Send for Circular.

CHEAPEST FERTILIZER BECAUSE THE BEST. PREMIUM BONE

Grows **WHEAT** and **GRASS**, equal to manure, at Half the Cost, and lasts twice as long.

With it one man, with the aid of one horse, can plant five acres per day, viz., open the furrow, cut, drop, and cover the seed and Fertilizers.

NASH & BRO., Manufacturers, 7 College Place, N. Y.

The Three Potatoes.

EARLY OHIO.—Earlier than Early Rose. It is ranked by general consent, by all who have tested it, in earliness, yield, and quality combined, at the head of the early potatoes.

BURBANK.—A medium late. A prodigious cropper, flesh remarkably white; quality excellent.

DUNMORE.—A splendid late sort. A greater cropper than the Peerless, which it resembles in form, while it is far better in quality.

Each, per barrel, \$4.00, per bushel \$2.00, per peck 75 cts. My Illustrated seed catalogue free to all applicants.

JAMES J. H. GREGORY, Marblehead, Mass.

Perfection Seedling Potato: yield 896 lbs. from 7 ounces seed. Price, 1 lb. 75c., 3 lbs. \$1.50 pre-paid. 1/2-pk. \$1.50, 1 pk. \$2.50, by express. J. W. Lounsbury, Cannon's Station, Ct.

"GET THE BEST."

HIGHEST AWARD at the CENTENNIAL.

Cheap, because so well made, durable, and efficient. Nine sizes made, churning from one, to 150 gallons. Warranted to be exactly as represented. Sold by all dealers in really first class Farm Machinery. **PORTER BLANCHARD'S SONS, Concord, N. H.,** Sole Manufacturers. Send for Circulars.

COW MILKER.

I have a **MILKING MACHINE** that will milk any cow in five minutes, clean. Its size is so small that it can be carried in the vest pocket. No more short teats or sore teats by bad milking; no more dirty or filthy milk. It can be used by a small boy; my boy of ten years milked to-day ten cows in less than one hour. I can supply the machine for \$5 each, to those who wish to try it, or it can be seen here at any time. **WM. CROZIER,** Northport, Long Island, N. Y.

The Rectangular Churn.

Simple, efficient, and always reliable. No inside fixtures. Fifty per cent in labor saved over any other churn. Five sizes made. The Highest award given over all competitors at the late Dairy fair in Chicago. An energetic man wanted in every town, to act as agent. One churn sent at wholesale where we have no agent. **CORNISH & CURTIS,** Fort Atkinson, Wis.

Over 5,000 Now in Use.—The Best **MILK COOLER and WARMER** IN THE WORLD

FOR RAISING CREAM.

Can make butter all seasons of the year. Will make twenty-five per cent more butter, fifty per cent better butter, with seventy-five per cent less labor, by using the **IRON-CLAD MILK PANS**, with great improvements for 1878. Made for any sized dairy, from five to five hundred cows. Estimates given for furnishing creameries. For Circulars, Price List, &c., address

BUNNELL & BROWN,

(Patentees and Manufacturers, and General Dealers in Dairy Implements).

Guilford, Chenango Co., N. Y.

The most effective, simple and convenient yet invented. Works 30 lbs. in less than 5 minutes, thoroughly working out buttermilk and mixing the curd. **AGENTS WANTED.** Send for circular.

A. H. REID,

6 N. Eighteenth St., Philadelphia Pa.

COOLEY SYSTEM

FOR

Butter and Cheese.

All the cream between milkings. No Skimming, no dust, no flies, no spoiled messes. Milk sweet for use after all the cream is off. Send stamp for circular.

Vt. Farm Machine Co., Belkows Falls, Vt.

LILLY'S BUTTER-WORKER

The cheapest and best Machine in the market; no hard labor required. Try it, and see for yourselves. Only \$15 for a thirty pound machine that will take all the milk out with five minutes' work.

HENDERSON & CO.,
316 Race St., Phila., Pa.

BUTTER COLOR.

After fair trials and severe tests it was awarded Centennial Prize Medal. WHY IT IS SUPERIOR TO ALL. 1st. It has no taste or smell, and is as harmless as water. 2d. It is liquid. 3d. It is easy to handle, and is mixed in cream before churning. 4th. It produces a color resembling June Grass Butter. 5th. It is the only article that will color the butter and not the buttermilk. 6th. It gathers all butter materials, increases the weight more than will pay for the color used. It is the best ever known. Send your address on postal card for my receipt book, free. It tells how to make butter, pack, preserve, extract rancidity.

MRS. B. SMITH, 327 Arch St., P. O. Box 1954, Phila., Pa.

SPAIN'S

PATENT CHURNS.

GRAND CENTRAL PREMIUM

30 BALES PER HOUR. 10 TONS IN A CAR.

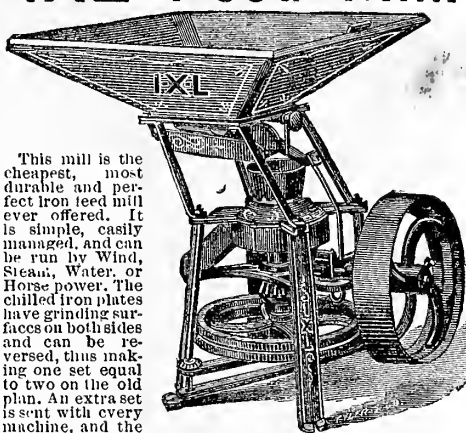

The Chamberlin Screw Stump Machine.

after 10 years test, its superiority over all others, by its great exhibition of strength and durability, combined with cheapness and ease in pulling all classes of stumps. The Company's challenge of \$1000 for a stump machine which would excel theirs, has stood since 1867 without being taken. They build 6 different sizes of machines, to pull all kinds of stumps. They make Subsoilers and Ditching Plows. For Particulars, Prices, etc., address **THE CHAMBERLIN MFG CO., Olean, N. Y.**

RUFUS L. COLE, PRODUCE COMMISSION MERCHANT, 141 Reade St., New York. Established in 1852. Market reports and shipping directions sent free on application.

IXL Feed Mill.

This mill is the cheapest, most durable and perfect iron feed mill ever offered. It is simple, easily managed, and can be run by Wind, Steam, Water, or Horse power. The chilled iron plates have grinding surfaces on both sides and can be reversed, thus making one set equal to two on the old plan. An extra set is sent with every machine, and the two sets will grind

Four Thousand Bushels of good Feed. New plates can be had for \$1.25 per set. These mills are built wholly of iron, (except the Hopper), are strong, efficient, and durable. Thousands are in use on Stock Farms—every one giving excellent satisfaction. Every farmer should have one and grind his own Feed.
 Send for Catalogue and Price List to
U. S. WIND ENGINE & PUMP CO., Batavia, Kane Co., Ill.
 Manufacturers of Halladay Standard Wind Mills.

Big Giant Corn Mill, Every Man His Own Miller.

The only Mill that will grind Corn with Shuck on without extra expense. The only Mill grinding Corn and Cob successfully that will grind Shelled Corn fine enough for family use.
 Grinds twice as fast as any other Mill of same size and price.

MANUFACTURED BY
J. A. FIELD, SON & CO., 922 N. 2nd St., St. Louis.
A. B. COHU, Gen. Agent, 197 Water St., New York.
ESTABLISHED IN 1844.

BRICK AND TILE MACHINE.

TWENTY YEARS standing as a **TILE MACHINE**, and without a rival as a **BRICK MACHINE**. For circulars address

The Best Fanning Mill in the World.

BUY THE A. P. DICKEY Fanning Mill.

No good Farmer can afford to market dirty grain. A moderate quantity of grain, well cleaned, brings a better price than the next grade in dirty condition.

Address **A. P. DICKEY, Racine, Wis.**
A. B. COHU, 197 Water St., N. Y., Agent for New York and Export Trade.

SAW MILL FOR THE PEOPLE.

This patent portable Mowing Saw Mill is adapted to any locality, will saw any kind of logs, and will do as much work (power and bands being considered) as the best Circular Mills. Its frame, head-blocks, and working parts are of the most substantial and permanent kind, being made entirely of iron and steel. It is usually set up and started in from one to two days time. It is generally driven by threshing engines of not exceeding ten horse power. It cuts from 200 to 400 feet of inch lumber per day. The Mill and Engine may conveniently be operated by two men. Send for circular.
INDIANAPOLIS IND. CHANDLER & TAYLOR.

THE

GLOBE NAIL.

THE BEST HORSE SHOE NAIL EVER MADE.

About ten years ago the **GLOBE NAIL COMPANY** of Boston, put on the market the first pointed, polished and finished Horse Shoe Nails ready for driving. Previous to that time all Horse Shoe Nails were pointed, and most of them made, by the shoers in their own shops at the rate of but six pounds per day.

The **Globe Nail** was at once found to be much cheaper and better than any then in use. It soon became so popular that all manufacturers of Horse Shoe Nails were compelled to make their Nails to resemble the **Globe**. For the last ten years it has been the model. Each year the Nail has been greatly improved in quality, and to such a point have we educated the shoers that now they will hardly use a nail unless it is absolutely perfect.

600 lbs. Finished Nails per day.

At the Centennial Exposition in Philadelphia, we were awarded the Medal and the following report, far stronger than that given upon any other Nail:

INTERNATIONAL EXHIBITION, 1876.
 U. S. CENTENNIAL COMMISSION.

[BUREAU OF AWARDS.]

PHILADELPHIA, June 23, 1876.

No. 239, **Globe Nail Co., Boston, Mass.**

Horse Shoe Nails, Pointed, Polished and Finished. The uniformity in size, smoothness of finish, hardness and tenacity of the iron, closeness of fibre, and excellence of the head and point, the tensile strength of body, and riveting properties of these Nails, unite in making them of the very highest class of manufacture.

Recommended an Award of Merit.
DANIEL STEINMETZ, Phila., Chairman,
J. D. IMBODEN, Richmond, Va.,
CHARLES STAPLES, Portland, Me.,
G. L. REED, Clearfield, Pa.,
DAV. MCARDY, Aberdeen, Scotland,
T. DIEFFENBACH, Germany,

Group Judges XV.

We annex a sample of the testimonials we receive daily from all parts of the country:

St. Louis, Mo., June 8, 1877.

GLOBE NAIL CO., BOSTON, MASS.

Gentlemen: Find enclosed advertisement and postal card concerning your Nail. (Referring to a scurrilous advertisement and postal card, disparaging the **Globe Nail**, circulated by a rival manufacturer over the humbug signature of "Humane Society for the Prevention of Cruelty to Animals." No Society bearing that title ever existed.) As I take a great interest in the prevention of cruelty to animals, —horses in particular,—I desire to say a few words in favor of **The Globe Nail**. Though I am not a very extensive Horse Shoer, yet I have used enough Nails of the different makes to speak knowingly. I have used the **Globe Nail** in my shop and on the race track for six years, on all classes of horses, from the heavy draft horse to the tender footed running horse; and I can safely say it has no superior in point of Toughness, Shape, and Finish, if it has any equal. I have used about fifteen hundred pounds of **Globe Nails** a year for the last six years, and in that time I have found four imperfect Nails, two of which I returned to you about two years ago and received in return four perfect ones, for which accept my thanks. If my men had no better sense than to drive those imperfect Nails in a horse's foot, I would not consider it the fault of the Nail if the horse was lamed. If bosses would look more to the competency of their men and less to trying to get shoeing nails a few cents a pound cheaper, we would have fewer lame horses. I know for safety and durability, with a man who understands his business, to drive them, your Nails can't be beat. I am willing to pay, without any suit for all horses that are lamed in my shop by using the **Globe Nail**. As long as it is made as at present, I shall continue to use it, even if I could get other Nails for nothing. I consider it the safest Nail that was ever driven in a horse's foot.

Yours Very Respectfully,
 (Signed), **P. H. O'NEILL,**

Horse Shoer, No. 1007 Broadway.

P. S.—I think I could get every boss in St. Louis to sign this if I thought it necessary. **P. H. O'N.**

The best Horse is sure to win. SO CLEAR THE TRACK FOR THE

"The best work on the diseases of animals in the English
language."—*Country Gentleman*.
Sent by mail from the Author for \$3.

ANVIL & VISE COMBINED.

3 Sizes, No. 1, weight 40 lbs., \$4.50; No. 2, weight 25 lbs.,
\$3.75; No. 3, weight 14 lbs., \$3.00. The face of the anvil is
chill hardened, rendering it of sufficient strength and hard-
ness to withstand all ordinary usage. Every farmer should
have one. Terms cash. Delivered on cars at Worcester.
RICHARDSON MANUFACTURING CO.,
SOLE MANUFACTURERS. Worcester, Mass.

Serviceable Silver-Plated Ware.

"Silver Steel" and "Albata" Silver-Plated.
Save the retailers and jobbers profit, and buy direct
of Manufacturers at Wholesale Prices.

An opportunity is now given to buy any of the silver-
plated ware manufactured by us direct. The goods are
made of good durable metal and will wear for years.

These are not cheap brass goods, like the
so-called "Premium Silver Ware," with which
the market is flooded, but are warranted as
represented. Remember, brass
goods are poisonous!

The entire set (59 pieces)..... \$11.00

Since our former advertisements appeared, we have decided to give the readers of
the *American Agriculturist* a higher grade of goods than those heretofore adver-
tised. Not that the others did not give perfect satisfaction, but we feel that the new
designs (made expressly for this trade) will, in quality and finish, be more desirable,
and well worth the small advance in price.

All sums over \$1 should be sent in Registered letter.

Address

BEATTY

Celebrated
PIANOS AND ORGANS. Best in the World.

BEATTY PIANO. Superb, extra Grand Square style, No. 66½. Fine Rosewood. 7½ octaves, all large round corners, elaborate extra moldings, as shown in cut, fine scroll desk, beautifully carved legs and pedals. Beatty's very latest full iron frame and excelsior overstrung scale. Weight (boxed) over 1,000 pounds. Other manufacturers' Catalogue

Price.....\$900.00
I will sell, boxed and delivered on cars, this magnificent Grand Square Piano, retail price by other manufacturers for similar instruments \$900, for only \$260 net cash, with order, money to be forwarded with exchange on New York.

Elegant Style with Valuable Improvements.

Sweetest Toned Parlor Organ ever made.

BEATTY ORGAN. I will sell, boxed and delivered on cars, this magnificent Parlor Organ, brand new, retail price for similar by other manufacturers, \$340, for only \$95 cash with order, to be forwarded with exchange on New York. This Organ is five octaves, three sets of reeds, 13 stops. Solid walnut case, highly finished, and weighs (boxed) about 350 pounds.

CAUTION.—The public are particularly cautioned against bogus instruments which are being palmed off as genuine Beatty celebrated Pianos and Organs, and particularly from parties in the West and South-west, where this detestable trickery has been extensively practised on the reputation I have gained; also, against the miserable knavery of would-be respectable manufacturers and dealers in this country and elsewhere in procuring my instruments and keeping them knowingly in very bad order, that purchasers may be prejudiced thereby against them and in favor of their own manufacture. As to their assertion that I do not manufacture my instruments, I am abundantly able to meet and prove to the contrary; also, beware of imitation and anonymous circulars, quoted from certain trade journals—write for explanation. I have placed skilled detectives on the track to ascertain the originators of these slanders, and if successful will prosecute them to the fullest extent of the law. **Read what is said of these Celebrated Instruments:** P. H. HANN, Cashier First National Bank, Washington, N. J., says: "The Piano gives the most perfect satisfaction in every respect, after being thoroughly tested." J. L. EVERETT, Cashier Broadway National Bank, New York City, writes: "Organ received. I am fully satisfied with the instrument." Wm. Underdown, Cashier Merchants' National Bank, Philadelphia, writes: "I am glad to say that the Organ continues to give us entire satisfaction." You are at liberty to send any one to see it." In order to more generally introduce my Celebrated Instruments, I am induced to make the above liberal offer. All instruments fully warranted for six years. **Special Offer** now ready on all styles of the world-renowned **BEATTY PIANO**, Grand, Square, and Upright, and **BEATTY'S** celebrated Golden Tongue, Parlor, Church, Hall, and Grand Cabinet **ORGANS**. Over sixty thousand now in actual use in this and other countries, and all giving entire satisfaction. Sweetest tones, most perfect Pianos and Organs ever manufactured in this or any other country. I challenge the world to equal them. **NEW PIANOS**, for which other manufacturers exorbitantly charge \$1,000, only \$297. **Electric \$650 Piano**, only \$175. **Superb \$275 mirror-top Organ**, only \$105. **Parlor Organ**, retail price by local agents \$300, only \$86. **Extra fine \$280 Parlor Organ**, only \$65. No better instruments can be made, and I challenge comparison. You can order direct from this advertisement, as nothing can be saved by correspondence on these prices, as these are made solely to introduce them in a new locality where I have no agents. Illustrated paper, containing testimonials from thousands who are using them, sent free. Address

DANIEL F. BEATTY, Washington, New Jersey, U. S. America.

INTERNATIONAL EXHIBITION For Agricultural Machines & Implements, HAMBURG, 1878.

From the 13th to the 17th of June, 1878, under cooperation of the Section for Agriculture and Horticulture, at Hamburg, and the Union of German Manufacturers and Dealers in Agricultural Machinery, an International Exhibition of all kinds of Agricultural and Garden Implements, will be held in Hamburg, Germany. It is well known that the endeavor of the above named Union has been to liberate manufacturers from the necessity of sending their goods to all Agricultural Exhibitions, whether large or small, enabling them thus to sell their manufactures at lower rates to the farmers. This result is intended to be obtained by limiting the number of exhibitions to the commercial centers of the German Empire, to be periodically repeated. For Northern Germany, Hamburg appears to be the most favorable place, where the various railroads, etc., connect with the seaport, and this leads to the hope that foreign nations will be represented there, so that the farmers and peasantry who will visit the exhibition may have the opportunity of witnessing a complete collection of all kinds of tools for husbandry, and systems in all parts of the world.

Plans and directions for sending to these International Machinery Markets, will be sent, free of charge, from the office of the undermentioned committee, 25 A B C Strasse, Hamburg. The committee for the International Agricultural Machinery Exhibition at Hamburg, in 1878.—**ALF. VON OHLENDORFF**, President; **HELM. SCHEMANN**, Treasurer; **DR. MRS. OLD FOGY DOES NOT USE THE ROBBINS WASHER.

MRS. COMMON SENSE DOES. TAKE YOUR CHOICE.

TO MAKE MONEY SECURE AN AGENCY

FOR THE

CELEBRATED

ROBBINS FAMILY WASHER.

This machine has been ON TRIAL for the past six months in every State and Territory in the Union, and the almost unanimous verdict of housekeepers is this: "Your Washer has proved a complete success." Some of the reasons why this popular verdict has been reached may be found in these facts:

The Robbins Washer is an entirely NEW MACHINE. It is constructed upon a NEW PRINCIPLE—that of forcing water by downward pressure through the fabric. The dirt or discoloration is removed by water force—there is no rubbing or friction about it. This principle is the only one that has ever been successfully applied to the cleaning of fabrics by machinery. All others have failed in one or more essential points. The Robbins Washer will cleanse perfectly, without rubbing, all kinds of wearing apparel, table or bed linen. It will not injure the most delicate fabric. It is the greatest bleacher extant, and for this purpose alone is worth ten times the price of the machine. It is simple, self-operating, never gets out of order, and will last a lifetime. It saves time; it saves labor; it saves material.

By purchasing a ROBBINS WASHER you can count the hard drudgery of the washboard among the things of the past.

Therefore, we confidently say to every housekeeper in the land, You want a ROBBINS WASHER. You cannot afford to be without one. It will pay to buy one.

THE RETAIL PRICE IS ONLY \$3.50.

Sample to those desiring agencies, \$3.

In bringing the Robbins Washer before the public it becomes necessary to take into brief consideration the

ART OF CLEANSING FABRICS,

which, although so common, is yet imperfectly understood. Having had a first-hand experience in the laundry business in connection with first-class hotels, public laundries, asylums, hospitals, &c.—we know whereof we speak. The numerous devices of friction rollers, pounders, squeezers, dashers, agitators, steam wash boilers, &c., have all done very well, so far as it was possible for such principles and devices to do. But they have all failed in one or more of the three essential points, viz.: The saving of labor, the wear and tear of clothing, and the perfectly extracting the dirt or discoloration—all of which are accomplished by the ROBBINS LITTLE WASHER.

WHAT IS IT THAT REMOVES THE DIRT?

You may ask all washerwomen and housekeepers, and your answer from the majority will be: "Plenty of elbow grease;" or, in other words, plenty of hard, laborious rubbing on the washboard. And such is the case, for you first have to rub soap upon the cloth, then you have to rub it in to make the dirt soluble. But does that remove it? No; to do that you must first dip it in the water, and then rub it in again to force water through the fabric. That is what removes dirt after being softened by the chemical action of the soap upon it.

The way in which this could be the most economically accomplished is what we have so long and patiently sought after, and at last a principle has been demonstrated that in uniting all the above named, in

THE PRINCIPLE OF THE LITTLE WASHER

is embodied all the essential points. First, we have the desired beat, which expands the fabric and causes it to discharge the dirt. Second, we obtain a powerful suction beneath the clothes, which causes a rapid downward current of water force through and through them, thereby removing the dirt. Third, we use a large body of water, which holds the dirt in solution. Thus we cleanse thoroughly, rinsing the clothes as usual, being all that is required to complete the operation.

The Washer is composed of solid galvanized iron, which will not rust or corrode. There are two sizes—the No. 1, or family size, for ordinary household use; and No. 2, or hotel size, suitable for country hotels, boarding-houses, laundries, &c.

OUR METHOD OF HANDLING.

We want agents everywhere throughout the United States, in every State, county, town, and hamlet. The retail price of No. 1 Washer is \$3.50; of No. 2 Washer, \$5. But we sell sample machines of No. 1 size at \$3; No. 2 or small hotel size at \$4. Canvassers for this Washer can make more money with it than with anything ever before offered to the public. As, for instance, we established two agencies to test the sale of the Washer upon its merits—one in Naugatuck, Conn., and one in Providence, R. I. The former, Mr. Charles Daniels, in a town of about 2,000 inhabitants, sold by canvassing in two weeks eighty-two Washers. In the latter place Mr. James Roberts, now of Naugatuck, Conn., sold in less than three months, without canvassing or advertising outside the store, over 500 Washers. A thing never before heard of.

TO PERSONS OUT OF EMPLOYMENT

we would say, if you want to secure a paying business, now is your time. Do not wait till the best territory is taken up, but send at once for sample machine and go to work. By following instructions you can sell to nearly every family in your neighborhood. Others have done it, and there is no reason why you should not. Full directions and instructions accompany each machine. Also, special terms to agents, circulars, testimonials, &c.

All orders must be accompanied with cash. Remit by money order or registered letter to

Delivered on cars at Worcester.

RICHARDSON MANUFACTURING CO.,
SOLE MANUFACTURERS, Worcester, Mass.

THE "Model Piano."

PRICE \$150 to \$200.

The "MODEL" is a beautiful little Upright or Cottage piano; it is manufactured from the best materials that can be procured; the workmanship is excellent, and its durability is guaranteed; it is small, light, and occupies but little room, is easily transported, and above all the "MODEL" is sold at about one-third the price that is usually paid for any other reliable piano. For the above reasons, it is very suitable for people of moderate means, and those living in small houses; but it is especially adapted for beginners, and on account of its low price, commends itself to every parent, because it possesses all the principal features of the finest piano, and has none of the numerous disadvantages of the cheap organ.

For full particulars write for illustrated pamphlet, and state where you saw this notice.

BLACK DORSET PIGS. — Drawn and Engraved for the American Agriculturist.

Those who have not traveled in European countries, can hardly realize the strongly marked and peculiar distinctions, which exist between localities that are very near together. "So near, and yet so far" apart are these different localities, that the stranger is surprised, if not bewildered. Thus in the geographically small country, Great Britain, which has but a little larger area than the State of New York, there exist not only many different languages, dialects, customs, and habits, but a very large variety of domestic animals. Several different races of horses, no less than nine distinct breeds of cattle, more than that number of breeds of sheep, and an astonishing variety of black, white, spotted, large, and small swine. A state of things like this could not occur in America, and it is owing to the peculiar character of the British people, slow to change, strongly prejudiced, obstinate even in what they think proper, and averse to travel and removal, that this curious condition of things exists. Here we are apt to change, fond of new things, and in fact anxious to discover something new, and always

ready to overthrow all our plans, and to try experiments in some new direction. Thus, with us, in a few years a breed of animals, which may become popular, spreads here and there over the whole country, and becomes generally distributed. Our people move frequently from east to west, and carry with them some old ideas, but rapidly appropriate those which they find current in their new homes, while in England there are herds and flocks, which have been kept continuously for a century. It is to this peculiar character that we owe the different breeds of pigs that have been imported from England; the Essex, Berkshire, Suffolk, Yorkshire, Lancashire, and others. Doubtless we have become possessed of the best of English swine, although there are breeds or varieties of them which are still generally unknown with us. Among the latter is that which forms the subject of the above engraving, the Black Dorset. This is undoubtedly very nearly the same, in all practical respects, as the well known Essex breed, which has become so popular in this country. The origin of the Black

Dorset is as follows:—About 30 years ago, two black sows were procured from Turkey by an English gentleman named Coates. These were bred to a Chinese boar, and the progeny were, in turn, bred to a Neapolitan boar. Since then, the blood of Mr. Fisher Hobbs' Essex swine has been infused into the breed, and in the end the result is a black pig so much like the Essex, that the difference is only evident in the name. They have all the excellent points of the Essex, with perhaps a tendency to greater size; having been brought to weigh 300 lbs. at 9 months, and 600 lbs. at 18 months. From the Neapolitan they inherit a fine hide, and thin hair, with the consequent tenderness and impatience of cold and rigorous weather. As with all rapid feeders, the flesh is soft, and the fat, oily, when forced to their utmost growth; when moderately well-fed and grazed for a season, or subsisted upon the waste of a dairy, the flesh is of superior quality, and not over fat. The original breeder of these swine is still living, and has been awarded a prize annually in twenty-four out of twenty-five years.

AMERICAN AGRICULTURIST.

NEW YORK, APRIL, 1878.

The active work of the year is now about to begin, over a large extent of country, and it may be well to consider a few plain and practical statements, and their bearing. Labor is the only source of wealth. Labor creates nothing; it only adds to already existing matter that quality of usefulness by which it is made to increase the general wealth. Wealth is simply the accumulation of the products of nature, and of our own industry—stored up for future use. Labor is set in operation by energy, and is guided by intelligence. An energetic man is industrious, and is tenacious of purpose. It is intelligence which enables us to make the most of our resources and to apply our labor most effectively. Unless energy is controlled by intelligence, physical or bodily labor is wasted uselessly. Mental labor plans, invents, arranges, and directs bodily labor, and makes it productive in proportion to the accuracy of the reasoning which incites it. The bodily labor of one man, or that of thousands of men, may be set in operation or guided by the mental labor of one man. Mental labor is therefore more effective and more valuable than bodily labor, and its value is to be measured by the value it adds to bodily labor. The mental labor which invents a plow, a mowing machine, or produces a book, may be of immense benefit to a whole country, or even to the whole world, for it may serve to increase many times the results of the labor of millions of men. So the mental labor or intelligence of the man who uses a plow, or a harvester in the best manner, or who reads the book to the most profit, becomes worth to him many times more than his muscular force, because these may enable him to do many days' labor in one, without any physical weariness, and so add to his actual wealth and his comfort. Thus it is seen that the mind and the hand must unite together, to make the labor of each effective; and that the mind may enable the hand to very greatly increase its usefulness. Work on the farm deals with things that are hidden to the sight, and need to be clearly understood; and there is no other physical labor performed in the world that needs more to be guided by the labor of the mind, than the cultivation of the soil, the rearing of stock, and the conversion of field products into finished articles for sale, such, for instance, as meat, butter, cheese, milk, etc. The result of all

this is, that a farmer should be a studious, thoughtful man, as well as an energetic industrious worker. He must also learn to stick to one thing; to persist in his chosen course; to be patient and persevering, and to strive to make his labor skillful and effective. With these qualities, there is no man surer of a reward for his labor, nor of better pay for the best quality of work.

Hints for Work.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every paper, from the latest experience and observations, by practical men in each department.]

The Plow is already at work in thousands of fields, while a few are yet kept idle by a sodden soil. Caution should be used lest the plow be put to use too soon. No furrow should be turned while the soil is wet. When the mould-board is smeared, and does not brighten in the soil, or when the furrow is pasty and does not crack open and fall apart loosely, as it is turned over, the soil is too wet, and will be injured by plowing. Make haste slowly in plowing.

Make a Note of It.—A little note-book for the vest pocket may be made by folding a sheet of paper until it is about 2 inches long and 1 inch wide. Stitch this into a pasteboard cover, cut the edges, and keep the book in the vest pocket with a piece of lead pencil. Note down in this every thing that needs attention as it occurs, and in the evening, either dispose of it, or make a more permanent memorandum. Having practised this method for years, we can commend it as very useful.

Spring Wheat.—In spring wheat sections this is the first crop to be put into the ground. Where it will grow, it will succeed all the better for the best culture. Unless more than 10 bushels of grain per acre can be harvested, it is labor lost to grow this crop. It would be better to raise

Oats.—Last fall we sowed half an acre of Tennessee winter oats. At the present time they are alive, and although the leaves are yellow, the hearts are green. The greatest danger is now over, and as they have been exposed to a severe drouth, constant freezing and thawing, and a temperature of 6 degrees below zero, they may be considered as a safe crop in ordinary seasons. If they can be acclimated to stand our most severe winters, they will be very valuable, and will be widely sown hereafter. Spring oats should be sown rather thicker than has been usual. Three bushels per acre is better than 2½ if the ground is made rich enough, and

The Ground Should be Made Rich Enough to grow the largest possible crops; else we are laboring with our hands and not with our heads, and unprofitably. Now that we have the most useful artificial fertilizers, specially prepared for all crops, by honest and responsible dealers, there is no excuse for poor crops, unless the farmer is too poor to procure these fertilizers. In that case he should cultivate less land, and learn to grow the largest crops, by better work and more liberal fertilizing.

High Farming is simply making the most of our resources. It is simply putting our work where it will do the most good, and suffering no wastes to exist. It requires skill more than money, and good management rather than costly tools, fine stock, and showy buildings. It is not altogether in burying miles of tiles in the ground, but in bringing our fields under such a degree of cultivation, according to our means, as will produce crops with the greatest profit. The farmer who gains the most from the least outlay, is a "high farmer."

Roots.—No other crop is more profitable than a good root crop. Mangels and sugar-beets are the most valuable of these crops. For these the ground should be prepared this month. Full directions for their cultivation are given in an article elsewhere. An Improved Yellow Globe Mangel, and Lane's Imperial Sugar-beet, are the best kinds in cultivation. One of the most recent, and best approved Globe Mangels, is figured on page 137. A mixture of guano, superphosphate of lime, and potash salts, will make an excellent fertilizer for these crops. The seed should be procured now,

ready for sowing late this month, if the season is well forward, or early next month.

Potatoes.—While the potato beetle is about, most farmers will plant early potatoes. They are out of the way before the great army arrives. But we look for a great diminution of this pest if potato growers will fight them at all times for a year or two. The open winter may have destroyed a great many, but enough will remain. Yet we would plant potatoes. There is no more profitable crop when planted on good soil, and well cultivated. The Early Rose is still the best for the general crop; Early Vermont is very good, and yields well; Snowflake is an excellent variety; Early Ohio yields well, and Burbank promises to beat its parent, Early Rose. This is variety enough for early sorts. Read the account of True's planter given last month.

Cultivation of Wheat.—The Travis horse-hoe, invented by a Michigan farmer, has been found very serviceable in cultivating wheat sown in drills. In time, we shall cultivate wheat as we do corn, with surprising benefit, and Mr. Travis is the pioneer in this modern, but much needed improvement.

Top-dressing Sod for Corn.—We doubt if any better disposal of manure could be made at this season than to top-dress at once the sod to be plowed by and by for corn. It is easy to grow 100 bushels of corn to the acre if we set about it. Many farmers are doing it. It only needs 2 good ears to each hill 3 feet apart each way; that is all. Having a corn that yields four or five ears to a stalk, it is as easy to grow 100 bushels per acre of corn as 25 bushels of wheat, with the manure and cultivation.

There is no Danger in Growing Too Much.—Great Britain imports eight hundred million of dollars worth of food every year for her 30 millions of people. Her farmers only raise 40 per cent of the food consumed in the country; the rest is purchased from abroad. We can have the bulk of this trade if we want it. And besides this, our working population is increasing very fast. There is no danger of over production, if products are properly assorted. Farmers, miners, and artisans, in due proportion together, will not flood a country with unsalable products. Plentiful food is the basis of prosperity.

Meadows and Pastures need a little stimulating fertilizer. A dressing of 200 pounds per acre of bone-flour, superphosphate, or guano, often doubles the yield. Nitrate of soda (150 pounds per acre) gives a rank growth, but the hay is not so nutritious as that from the phosphatic manures. Improved meadows mean more milk, cheese, butter, and beef. Along with the fertilizer, a scattering of fresh seed, timothy, blue-grass, red-top, and clover, mixed; and a good harrowing will be beneficial. All this may be done this month.

Horses.—A regular allowance of grain will now be needed by working teams. It is economical to feed ground grain. Ten quarts a day is a full allowance for a hard-worked horse. A pailful of moistened cut hay, with 3½ quarts of ground feed mixed with it, is the usual quantity fed to each of our horses. This feed is not too bulky, and when given nearly dry, has not the injurious effect on the wind of wet soft feed. The best feed is equal parts of corn, rye, or oats, and wheat-bran.

Cows.—In-coming cows should be treated with caution. Good hay is sufficient food for the month previous to calving. Watch the udder closely, and on the first appearance of heat and hardness, bathe it with cold water to reduce the inflammation, and insert a silver milking tube into each teat to draw off the milk as it may be secreted. In case garget has occurred previously, give 20 grains of iodide of potassium in a drink of water, and rub the udder with a mixture of 7 drams of glycerine and 1 dram of iodide of potassium. It is well to let the calf suck the cow if there is any trouble with the udder.

Calves.—By raising the heifers of our best cows, the stock will be improved. Every farmer should aim to keep only the best. A cow yielding only 8 quarts of milk a day does not pay for the feed, and should be replaced with a better one. We must look upon our live-stock as machines, kept for a purpose, and discard unprofitable animals.

Sheep.—As the days become warmer, ticks will

increase, and sheep will appear restless under their winter blankets. Give them shade on the cool side of a building, or put up a temporary shed in the field where they may escape the hot sun of noon-day. As the sheep begin to nibble the new grass, look out for scours in the lambs. If this appears, give a tablespoonful of a mixture of peppermint water with prepared chalk, and a little ginger. For the ticks, see hints last month.

Pigs need clean dry pens, and supply breeding sows with cut straw, chaff, or sawdust, for litter.

Oxen, when at work under a hot spring sun, will suffer from the heat. Give them frequent resting spells, and water, with some bran stirred into it.

Manure should be turned over early in the month, so as to have it rotted as much as possible for use in hill or drill crops. Those who have heeded our advice, to cut all the straw and stalks, either for fodder or litter, will find the handling of the manure heap an easy task. Those who have not, will probably regret the failure, and resolve to do better.

Poultry.—Many hens will now have laid out their litter, and become broody. Give sitting-hens clean nests of soft hay, and do not set a hen that is infested with vermin. Put such a one in a close coop lined with tarred roofing-felt, and apply grease to her legs and under the wings. Houses may be kept free from vermin by cleanliness, and using grease and kerosene oil on the perches.

Sundry Matters.—Haul out a liberal allowance of the best manure to the garden, with a load of good cow-manure for the flower beds. The satisfaction will come when the effects are seen. Raise the earth around the well, or cistern, to turn off surface water. Observe the strictest cleanliness in the stables and yards. Make channels for waste water. Raise the centers of roads and foot paths, to keep them dry, before the hurry comes on. If seeds of all kinds have not been procured, do this without delay. Be cautious in trying new kinds, and never risk the main crop in uncertainties.

Notes on Orchard and Garden Work.

There is rarely a season that is not regarded, for one reason or another, as "remarkable," yet a consultation of the records for a few years back, will show that the same "remarkable" seasons are not of so rare occurrence. Still we can not recollect when we have before had, near New York, blue-birds abundant at the end of February, followed in early March by other birds, in such numbers as to indicate that, in their opinion at least, we have an early spring. If the present indications (March 12th) continue, there will be a rushing time with all spring work. Those who act upon the principle of doing work whenever it can be done, are less likely to be crowded, than those who put off spring work, because it is not spring by the Almanac. The Notes for the past two months should be consulted, and all preparatory work hurried up.

Orchard and Nursery.

The Planting Season, if this weather continues, will be short, and the work must be pressed. There is little to add to last month's Notes.

Trees from the Nursery, if transported a long distance, may be injured in warm weather, in two ways. 1st. They may be dried out. This will be shown by the shrivelling of the bark on the twigs. For trees in this condition, open a trench in light, mellow soil, large enough to contain them, root and branch. Then, first seeing that the labels are all right, bury them entirely in moist, but not wet, soil, putting a stake at the roots as a guide in taking them out. Let them remain buried five days or a week, and, when taken out, they will be found perfectly restored. Another danger is, 2d, from

Overheating in Box or Bundle, causing the buds to push. We have received trees, long on the journey, the shoots of which had pushed two or three inches. It will be found that it is always the upper buds on the branches which start first, and the only remedy is to cut every branch back to a dormant bud—one that has not started—no matter if it leaves

the tree a mere stick with stubs upon it. This is severe treatment, but is the safest.

What Varieties to Plant, is a question often asked of us, and is one of the most difficult to answer. If the fruit is for home use, a succession from the earliest to the latest, will be needed. If fruit is to be grown for market, then it is necessary to know what the market requires. In all these cases, the fruit-growers in the neighborhood can give better advice than any one else, and we have never yet met a successful fruit-grower who was not willing to tell what he knew for the benefit of others. It is only quacks who have secrets. A recent request came from Central Massachusetts for us to name

Six Pear Trees that he could plant for profit. We named several, the fruit of which he might profitably dispose of in Boston at a good price, which could only be sold in New York as "cooking fruit." This merely shows that one should consult the tastes of his market in selecting varieties.

The Home Nursery.—Those who propose, in a year or two, to set out orchards, can well prepare for it now. They can buy from the nurseries root-grafts, or nursery stocks "in bud," i. e., stocks budded last year, on which the buds have "taken," and which will start into growth this year, from which the stock above the bud, must, of course, be cut back. These, the very beginnings of trees, can be bought very cheaply, and if set 18 to 24 inches apart in rows wide enough apart to be well cultivated, will, at the end of two years, give excellent young trees to set in the orchard, at a small cost.

Grafting Old Trees, to convert valueless kinds into better ones, should be done just when the buds swell. We can not repeat the directions for this every year. Grafting was described in full, with engravings, and made so simple that any intelligent boy can do it, in the *American Agriculturist* for April, 1877, which may be had, by mail, for 15 cents.

Books on Fruit Culture.—Every one who has an orchard, should have at least one book on fruit culture. A list of the leading works was given in these Notes in January last.

Insects.—Where the "Canker-worm" is troublesome, look to the barriers to prevent its ascent, and renew the tar or printer's ink upon the bands. Dead insects will often make a bridge over which the living may cross; a daily inspection is needed.

Fruit Garden.

LAST MONTH'S NOTES, in a great measure, indicate the principal work for this month, and as that will be planting, it can not be pushed forward too early. Early planting is desirable for every kind of fruit. In northern localities the

Winter Covering of strawberries and the tender kinds of raspberries will remain until the present month. Lift the raspberries, and tie them to the stakes or trellis, when all danger of severe frost is over, and open the straw, or hay, on the strawberry beds, over each plant, to expose it freely.

Gooseberries and Currants should have been procured last fall, or early this spring, but it may be done now if the plants have not started into growth.

Grapes.—The Notes of last month, together with the article on page 144, should induce those who have no vines to plant them, and will serve as a guide as to what, where, and how to plant.

Kitchen and Market Garden.

In all, except the most northern localities, the cold-frame plants will be set out, and the sashes which have covered them during the winter, will be doing service on other frames, in forwarding lettuce, radishes, etc.

Hot-Beds and Cold-Frames, in which seeds have been sown, will need increased care, as the sun gets warmer. Last month we indicated what this care is—abundant ventilation during the day, early closing of the frames, and covering in cool nights.

Early Sowing does not mean the same thing in Canada that it does in Georgia, yet there are in both localities certain things that may be sown first.

The Earliest Sowings, everywhere, are of Beet,

Parsnip, Early Turnip, Spinach, Radish, Peas, Leek, Onion, Parsley, and Cress. These should be sown first so soon as the soil can be worked, and all are to be sown where they are to grow, though Parsley and Leeks may be transplanted if desired.

Seed-Beds of Cabbages and other things to be transplanted, if not under glass, or in window-boxes in the house, as heretofore advised, may be made in a sheltered sunny place in the open ground.

Early Potatoes, to be early, must be planted at once, and if the soil is light and warm, no matter if a frost nips the tops, they will start from below.

Succession Crops.—Where the season has allowed of early sowing of Beets, Peas, Radishes, Spinach, and other early vegetables, succession crops should be put in every two weeks or so, until hot weather is likely to prevent their healthful growth—and this should be kept in mind all through the season.

Asparagus.—If new beds are to be made, get one-year-old plants, and give them all the room that can be afforded. The old directions for a family garden were, to put the plants 12 by 18 inches. This will do if no more space can be afforded, but market-growers find that the wider the space, the better the crop. Some who grow for markets, set the plants as wide apart as 6 ft. by 4 ft., and find this the most profitable for field culture. This would, of course, be impracticable in a family garden, where 2 x 2 feet will be wide enough. The old practice of manuring a bed to last for years is not now followed. The plants at setting should have a good supply of manure, and then an annual dressing afterwards. Asparagus should not be cut until the third year after setting.

Sweet Potatoes should be started about six weeks before they can be safely set out, which is, in the latitude of New York, about June 1st. This is a sub-tropical plant, and nothing is gained by putting it in the open ground until that is well warmed. In southern localities, the potatoes are "bedded out"—a pit is dug in a sheltered place, manure put in, and some soil placed over it. The potatoes are laid in, and, if large, cut lengthwise, and covered with about two inches of rich soil; the bed must be covered at night, and on cool days, with boards. In the Northern States, the potatoes are started in a hot-bed.

Odds and Ends.—Procure all the seeds you are likely to need, early....Read over Notes for the last two months....If you have no seed-drill, get one of some kind—it will pay for itself in one season, even with a small garden....Read Prof. Atwater's articles on fertilizers, in former months, as they apply to the garden as well as to the field. Try new varieties, all that you can afford, but do not give up standard sorts for novelties, however highly praised. Try new things, but go slow.

Flower Garden and Lawn.

The title really should be "The Lawn and Flower Garden," as in many cases the lawn is the first consideration; the lawn is the ground-work upon which the flower-beds, be they simple or elaborate, are to be displayed.

In making a lawn, it must be borne in mind that the work is to last for years, and that the soil must be as well prepared for the grass as if for the choicest plants. Draining, if needed, is the first necessity; to this must follow, abundant manuring, deep plowing, harrowing, and rolling. If the rolling discovers any weak spots, these must be filled in. The next question will be

Sods or Seeds?—If the lawn is not too large, and good pasture, or road-side turf, is to be readily obtained, it is better to use it; but,

In **Turfing**, it must be borne in mind, that to make a successful lawn, the soil is to be as well prepared as for sowing seeds. The turf should be of the best kind, and free from all weeds; and when laid, should be well pounded down. If any soft spots are found, they should be made solid.

In **Seeding a Lawn**, it is very desirable to lay all the margins along roads and paths, as well as the margins of flower-beds, with turf. Sow early, and, to insure an even east, divide the seed into three

or four parts, and sow in as many different directions. For kinds, see last month. Use the roller freely, and notice, mend, and re-sow all soft spots.

Sowing Grain with Grass, which is often advised, is not needed unless the lawn is sown very late.

Planting of shrubs and trees can not be done now, too soon. The planting of ornamental beds, usually done with tropical and sub-tropical plants, should be deferred until the ground is well warmed.

Ornamental Beds.—Experience has shown that European examples have little value for us, and that for ornamental work we must depend upon foliage, rather than upon flowers; and we may employ, for effect, plants with colored foliage, and those with broad leaves, like the Cannas and other similar plants, generally classed as sub-tropical.

Coleuses and Alternantheras.—Plants of this kind of course require a greenhouse to provide a stock. Those who have not such facilities, can produce ornamental effects later in the season with

Annuals.—Thus, some of the ornamental varieties of *Ricinus*, or Castor Oil Plant, are very effective; another very showy annual, judiciously used, is *Euphorbia marginata*. Then there are the different

Celosias.—Indeed, a consultation of the seed catalogues of the leading houses, will suggest various other annuals that may be used with good effect.

Hardy Perennial Plants should not be overlooked, as excellent bedding effects may be produced with these. We last year described a bed filled with the *White Anemone Japonica*, bordered with *Sedum spectabile*. Other combinations may be made.

Spring Bulbs, such as *Gladiolus*, *Tiger Flower*, and others, are to be put in as soon as the weather becomes settled. It is well to make two or three plantings for a succession.

Greenhouse and Window Plants.

Shade will soon be needed for plants under glass; this is best done by white-wash—ordinary lime wash, such as is used upon plastered walls. To make a gradual shade, this is flitted from the brush in drops, sprinkling the glass thinly at first, and increasing the spattering as the sun gets hotter.

Shade for Window Plants must be provided in a different manner; usually a screen of common cotton cloth, such as would be needed, were there no plants at the window, will be sufficient.

Harden-off will be necessary with all plants, whether in the window or greenhouse. This is accomplished, in either case, by free admission of air, whenever the outside temperature will allow.

Stripping the Greenhouse, and placing all the plants outside, is not now so much practised as formerly, as it is very easy to keep the house in an attractive condition not only by the use of the summer-blooming greenhouse plants, such as *Gesnerias*, and those of that family, but by the use of such showy annuals as the *Balsams*. Whoever has not seen the *Balsams* carefully grown in pots, can have no idea of the beauty that this flower is capable of. The same may be said of some other annuals.

Plants to go into the Border, such as *Geraniums*, will get too large by fall to be taken in again, and it is well to propagate others from cuttings early in the season to decorate the house next winter.

Bulbs.—The last of the *Hyacinths*, and other bulbs, will now be in flower. As soon as the flowers fade, turn out the bulbs, if the ground is open, in some spare corner, and they will in time resuscitate.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our daily record during the year, show at a glance the transactions for the month ending March 12th, 1873, and for the corresponding period last year:

TRANSACTIONS AT THE NEW YORK MARKETS.

Gold has been up to 102 1/2, and down to 100 1/4, closing March 12, at 100 1/4, (or nearly down to par), as against 101 1/2 on Feb. 12; 102 1/2 on January 12; 103 on December 12; 102 1/2 on Nov. 12; 103 on October 12; 105 1/2 on July 12; 104 1/2 on June 12; 107 1/2 on May 12; 104 1/2 on March 12, of last year....Though the receipts and sales of Breadstuffs, during the month, have been to a comparatively liberal aggregate, the course of the market has been far from satisfactory to sellers, who have been compelled to make further important concessions to buyers, especially toward the close, with a view to placing supplies promptly. Advances from Europe continue against the export interest, and serve to depress values. Flour and Barley close heavily and irregularly, on a tame movement. Wheat and Corn leave off irregularly. Of the purchases, on export account, were large quantities of Wheat for French, German, and other Continental markets; and of Rye, chiefly for Germany. Operations in Barley were much less extensive, as well for shipment, as for home use. Some revival of export demand has been noted for Oats....In the line of Provisions, the feature has been

at \$75,278,281. Of oysters, 4,000,000,000, valued at \$50,900,000. (This equals 100 oysters for every man, woman, and child, in the country.)

Sending Papers.—We again ask our friends who send us papers containing articles they wish us to see, to mark the articles by pencil or ink line (blue pencil is best), so distinct that it will readily catch the eye. The clerk who opens the paper mail can not possibly read, even the headings, of the articles in the hundreds of papers that come daily. Also notify us by letter or postal, by the same mail, of the sending of the paper. We now and then get a card—like the one at hand—saying: "I sent you last week a copy of," etc. The paper, not being marked, is no doubt on its way to the paper-mill, to be ground over. The Post-office rulings allow an article to be marked by a line, to call attention, but, of course, there must be no writing.

Much Delay and Disappointment result from mixing editorial and business matters in the same letter. A letter on business, of course, goes first to the business department to which it belongs, whether it relates to matters concerning the paper or to the book business. When those having charge of such matters have done with the letter, it is passed over to the editors. It may, and often does, happen, that a question for the editors, in this way, often loses a whole month, through the delay of a day or two thus caused. This may be avoided by putting the editorial and the business matters on separate sheets in the same envelope.

Supplying Experimental Fertilizers.—In proposing the Farm Experiments, described last month, and elsewhere in the present number, it became necessary to make arrangements at once with some one to supply the fertilizers to be used in the experiments. We consulted with several responsible dealers that were most accessible, and as the Mapes Formula Company were the first we met who cheerfully and heartily entered into the project, arrangements were made to have the fertilizers put up by them. The reason why we did not merely name the fertilizers, and suggest that they might be had of any reliable dealer, was because, in a first effort, it seemed desirable, important even, to have the work concentrated at one point, to secure the needed analysis and oversight, and the necessary uniformity in the materials furnished. It is due to Messrs. Wm. H. Bowler & Co., well-known dealers in fertilizers, at Boston and New York, to say that, on seeing our announcement, they at once offered to supply the trial samples on the terms named, and with all desirable guarantees. We would have been glad to have them do so, as we have every confidence in their ability and character; and we might say the same in regard to several others first-class dealers. But it is hardly practicable, at this time, to make any other arrangements than those announced last month. We hope some similar project may be carried out another season, embracing the entire country, and a number of those dealers who guarantee the quality of their articles.

Sale of Fine Jerseys and Family Cows.—Mr. Thomas Fitch, of New London, Conn., announces a sale of thoroughbred Jersey cattle and high-grade animals, bred especially for family cows. No breeder has been more successful than Mr. Fitch in making crosses on the Jersey with the effect of producing high milk and butter-yielding cows. This has been an especial business with him for more than 30 years. His herd numbers over 100 head of young and mature thoroughbred and cross bred animals, many of them being rich butter-makers, and all of them good. Mr. Fitch's announcement will be seen elsewhere.

Calcecake is the name adopted by the Averill Chemical Paint Co. for a very convenient article, which will allow those who wish to calomine their own walls to do so, if they have only ordinary skill.—The materials for the wash are in cakes, which need only to be dissolved in boiling water, to be ready to use. The shades are delicate and pleasing, and we have no doubt that the Averill folks have hit upon a most popular thing.

Lumps on a Horse's Shoulder.—"J. L. R.," Chillicothe, Mo. When collar-galls have irritated the bone of the shoulder, and hard lumps have formed there, they can not be removed; they are growths of the bone, and beyond the help of the surgeon.

Grass for Montana Territory.—"J. S. H.," Cheyenne, M. T. makes several inquiries, which we would have answered by mail, but he gave only the initials, as above. As stamps were enclosed, a reply by mail was probably looked for, but, of course, this is impossible. There is a hook on irrigation, in which all the information as to grasses for sowing, mode of preparing and cultivating the ground, making ditches, laying out meadows, and the manner of irrigating and

generally managing them, is fully given. This is "Irrigation for the Farm, Garden, and Orchard," by Henry Stewart, sent, post-paid, for \$1.50, by the Orange Judd Co. For planting along the ditches, the common cottonwood, or white willow, would be easy to procure, and would grow readily from cuttings. Oats should be sown as soon as the frost is over, and the ground is fit for working. Timothy-seed can be procured at Omaha, or Lincoln, Nebraska. The cost is about 5 cents per pound.

The Little Washer, made by Geo. D. Bissell & Co., Nantucket, Ct., having been advertised in our advertising columns for some time, we have received numerous letters concerning it. To such we would say: The washers in the market are of two kinds; in one the clothes are washed by rubbing, or squeezing, and in the other by a continuous flow of boiling suds over and through the fabrics. In an article on page 144, we have shown the difficulties that attend the introduction of all aids in washing, where the "help" (so-called because they hinder) are prejudiced against them: We have tried the "Little Washer" sufficiently to know that an intelligent person, one who is not "set agin" it, can make it a useful aid in the family washing. The same principle is employed in establishments for cleansing large quantities of fabrics. Where stupidity and prejudice combine against it, no domestic appliance is of any use.

The Asbestos Paints, made by the H. W. Johns Asbestos Mfg. Co.—To those who write, inquiring about these paints, we would say that we can not give a final opinion until five years after we have applied them. We can say now that they promise well. We used them last year on several buildings. The tints are pleasing, and the one who applied the paint found it to cover well. We used it upon both old buildings and new, and, judging from its workings, we should not hesitate, had we more painting to do, to use this.

Hybridizing Plants.—J. W. Tower. We wrote you a letter giving the title of the best work on the subject, but when we came to direct the envelope, we could not find the State—so our letter and yours kept company in the waste-basket.

Flax for Seed.—"J. B. G.," Rockwell, Iowa. When flax is sown for seed, one bushel per acre is sufficient. When it is thinly sown, the plants branch, and have many more seed-holls than when sown thickly. For the fibre, which should be fine, two bushels per acre are sown. Flax-seed should be sown early, about the time that oats are put in the ground.

Sundry Humbugs.

Alas for Russell & Co.! Has their glory departed? From a dozen of their circulars a day, the thing has gone down to three or more in a whole month! Those watches "valued at \$150.00," and those lots of jewelry "valued at \$250.00, \$280.00," and all sorts of other values—can they have been exhausted?...Our last intelligence as to this "Lot of Jewelry," comes from a jeweler in Laporte, Ind., who, just for the fun of the thing, had a \$280 lot of the "Jewelry" sent to him. He writes: "I find them to be a lot of very well finished, but worthless trash, the wholesale price of which

I would rate at \$5 to \$8."—Here is the testimony of an Expert, which those innocent people, who think that any one will give them more than a Dollar's worth for a Dollar, will do well to remember. Exit Russell & Co., but "powers behind the throne" are by no means dead. "Draw it mild," Messrs. E. & Co. Some one is now on the track of your latest developments.... We hope that our warning against

FARMERS GIVING NOTES

have been sufficiently strong and frequent to, at least, make the readers of the *American Agriculturist* stop and think a little before they get caught in such a trap as three of New Jersey farmers walked into. We again repeat, to not only farmers, but to all other readers,

BE CAREFUL HOW YOU SIGN a paper of any kind, AND TO ANY TRAVELING AGENT WHATEVER.—**DON'T SIGN ANYTHING.**

Many of these cases do not get into print at all, the victims bearing their losses in silence. The Trenton (N.

J.) "State Gazette" gives a recent case of this kind, and we mention it in brief, not to expose the folly of the victims—for men who are honest themselves are the most easily taken in by such scoundrels—but as a warning to others.

"Two men named Clarke" presented themselves as agents for a patent wind-mill. They sold the "right" (farmers, mind how you buy "rights," for they often turn out big wrongs), for Warren Co., to James De-roamer, Isaac Dehart, and Abraham Pursell. These gentlemen gave a note to these Clarkes for \$700.00. Having a note from well-known and well-to-do men, the Clarkes went to a neighboring town, where there was a bank, and had no difficulty in getting it discounted. But the Clarkes were well up in their business; they came back to the makers of the note, and told them that they could not get it cashed. The account ends thus: "The farmers then gave them \$700, since which time nothing has been heard of the agents, nor have the farmers received their wind-mill." We hazard nothing in predicting that those agents and that wind-mill will not be again heard of in Warren Co., N. J. The claps have made a clean \$1,400, and they will not again be found in Warren Co., or in any other Co. in New Jersey. Fourteen hundred dollars in a State no bigger than New Jersey is a big haul. Can we add anything to this plain statement of facts? This is a specimen of

THE SWINDLES UPON THE FARMERS

that are being practised all over the country. We would not say, "Have nothing to do with any traveling agent," as that would be unjust to many honest men who are engaged in introducing articles of real value to farmers; but we would ask every farmer to exercise proper business shrewdness, and to distinguish the swindler from the real seller. A few weeks ago a seller of mowing machine knife sharpeners, coaxed, worried, and finally bullied an honest man in Pleasantville, N. Y., into signing a note for a lot of worthless machines, and now the note is sued in a distant town, requiring as much expense for time and lawyers to defend, as the amount of the note itself (\$200). We may state it as a safe rule—if you can not make a trade without signing anything, you had better let that trade go by. The land is so full of swindlers, that there is no safety in any other course. So we repeat our caution—and it would be well if it were put up in large letters, where it can be seen daily—"With all strangers, with all traveling agents,

FARMERS, BE CAREFUL WHAT YOU SIGN."

Let no "Exclusive Agency," let no prospective profit, let no palaver of any glib-tongued salesman—no matter what he has to sell, no matter what hopes of a sudden fortune he may hold out—induce you to put your name to any kind of a paper. If one comes to you well recommended, if he is honest, he will willingly wait until you can find out if his credentials are true. Make no snap-agreements; jump at no great chances. Whoever comes along with an honest thing will be ready and willing to have it examined through and through. Deal with no others; and we now say to *You Farmers*—you for whom we have worked year in and year out in examining "Humbugs" of all sorts, we say, with renewed emphasis,

BE CAREFUL WHAT YOU SIGN.

MEDICAL MATTERS

are not many, but we can not say that they are dull this month, as we have one first-class one, worth a score of the common kinds. About a year ago, we saw a small sheet announcing it, but have only recently come into possession of the work, giving a full account of

"THE METAPHYSICAL DISCOVERY"

of one Mrs. Brown. In that remarkable paper, the "N. Y. Tribune," Mrs. B. speaks of her work as "the most valuable pamphlet in the world." We are quite sure that there is not another like it. "Metaphysical"—we should say so! We never met-a-physical, or physic-ing thing, that could begin with it. We can say, without any metaphor, that we never met-afore anything that proposed to work a greater metamorphosis in the system of medicine than this work; and we never met-a-physician who could meet and physic one equal to this metaphysician. The Indian doctors are nowhere. Metamora was a big Injun, but we never met-a-more astonishing piece of indian-doity than this metaphysical discovery. Whatever Mrs. B. may be on doctoring, none can dispute her literary ability in presenting her doctrine. We first received a paper called

"THE LEASE OF LIFE,"

which professes to be issued by the "Metaphysical University in New York." The "Lease" is not "signed," but it tells us at the very top of the first page what it is. For it says: "When the MUCUS MEMBRANE connected with the nose is plugged up—for want of suitable moisture—the death warrant of the body—is signed." This plugging is awful business, for we read: "There never was a fever since the world began that was not produced from a plugged-up head." Has this anything to do with a "plug-ugly?" Is one who wears a

"plunged" on his head any more liable to a "plugged-up head" than another? We read that: "The head is the seat of life, also the seat of death," which makes it rather hard on the head. But what can one do with a "plugged-up head?"—Ah, here we have it.

"THE METAPHYSICAL DISCOVERY"

courses through the *head* and *trunk* of the *body* as the rivers of the Sea course through the earth." And when we read below that "LANGUAGE FAILS to unfold the Treasure contained in the METAPHYSICAL DISCOVERY," we find the first statement with which we can agree—just so... Mrs. Brown has got this disease business down to a dot. She starts with asking us to "Consider that the Body is the Earth."—Well, we have seen some bodies where that consideration was not a difficult one.—"The hair is a field of grass," (that, probably, is the reason why some people have "hay-seed" in their hair.) "The eyes and ears are plants." This "Discovery" doesn't go around the body sort of promiscuous like, but it finds its way in through the eyes, ears, and scalp. So, to carry out the agricultural similes, she has "dew" for the eyes, and "rain" for the ears, and some stuff for the scalp analogous to "frost and snow," and we should judge by the venerable gentleman she uses so freely for a "figger-head," whose scalp is as bare as an egg-shell, that he has been subjected to pretty hard treatment, which is not surprising when we are told that the "Scalp-Renovator" is the "most thorough, logical and gentle cathartic in the world," and that it "enters the system through the canals of the head, and works wonders." Besides this remarkable paper, there is a large pamphlet of over 80 pages, filled with such farrago. A remarkable thing about it is the way in which Scripture is quoted; some of the allusions bordering closely upon profanity.

THE SAME OLD TUNE TO NEW WORDS.

There came to us a few days ago, a letter from a correspondent in Wisconsin, which enclosed a written circular, with the printed heading:

"CLARK & CO., ADJUSTERS OF CLAIMS IN THE U. S. AND EUROPE.

1,267 BROADWAY, NEW YORK, (22d February, 1878.)

N. S. T., Esq.:

DEAR SIR.—Is this your signature on the inclosed slip of paper? If so, you are entitled to a certificate of gold-mining stock valued at five hundred dollars. The money you sent in the letter, from which the inclosed slip was clipped, was invested on the general margin principle, which resulted in lawfully securing for you the certificate of stock referred to above. Now, if you will write to us, and return the inclosed slip, so we can compare it with your signature, we shall be sure the proper party will receive the stock. Respectfully, CLARK & CO. P. S.—State whether you wish the stock sent by registered letter or by express. C. & Co.

Within this letter was a small "slip of paper," which had evidently been cut from a letter to which it was the signature, on which was

"Respectfully, &c., N. S. T. —
Box 97."

This our correspondent admitted to be his genuine signature, but how it came into the possession of the New Yorker, was more than he knew, but being convinced that the whole thing was a "humbug," he left it with us to do with as we pleased. As the matter seemed worth looking up, we called upon Special Agent Sherrett, who has a sharp scent for frauds, and a most decided method of dealing with them when found. We saluted him with the information that we had a new scheme. "So have I," he promptly replied, "I was just thinking of you, as I have a bran new one."—We gave him our documents, and he had not read two lines aloud, before he placed his hand upon a letter upon the desk before him, and handed it to us, with a "look at that!"—and as he read the letter we had brought, we followed the lines, upon the one that had just been received by him, and, with the exception of the name of the person addressed, the two were the same, word for word. He informed us that he had been to the place, a building far up Broadway, in which offices are rented, but could find no one in. "I'll tell you what it is," said this shrewd officer; "this is another development of that old silver mining scheme, Russell & Co., and all the rest of it, and you'll find Elias at the bottom of it."—We became interested in the matter, and had one of the discreet and confidential young men in our office, try to find Clark & Co., and learn about the "stock." He had to make several visits before he could find any one in the building who knew of such firm; but at last ascertained the room occupied by these "adjusters of claims," and by going out of business hours, caught some one "at home." A very barren office had a few chromos setting upon the floor against the wall, there was a most venerable desk, and a stove, which, with a well-to-do-looking person with a gray beard, (and whose identity is more than suspected), mainly completed the furnishing of a most desolate place of business for parties engaged in adjusting "claims in the U. S. and Europe." The correspondent had sent us an order to get the money for that \$500 worth of stock, and our representative made

known his business. Immediately the venerable individual became a "known-nothing"; he wasn't "Clark & Co." at all; he only "represented" them. His business was selling chromos and jewelry, though there was nary a jewel visible. But he did know enough about "Clark & Co." to be sure that in the press of their "immense business," this letter was all wrong. It was misdirected in the hurry of their overwhelming biz. That letter was not intended for that particular man—a likely story, as the enclosed signature clipped from some letter exactly corresponded with the direction on the outside of the envelope. Not a blessed word of information as to stock, or anything else, could be extracted from their representative, concerning "Clark & Co." He was drier than a cod-fish—and our representative came away, leaving him with his chromos, his very rickety desk, and his stove, to report progress. But other parties had an interest in "Clark & Co." A gentleman in Missouri had received a letter, word for word like that of our Wisconsin friend—and another in Fall River, Mass., had been similarly favored, and both of these sent their documents to Superintendent of Police, Walling, who put the ease into the hands of Capt. Williams to "work up." Capt. W. visited the business place of "Clark & Co." several times, but no one was in. Knowing that these chaps—whose doings are entirely by mail—would be likely to be "at home" to the letter carrier, awaited his time; the letter carrier appeared, the door was opened at his knock, and Capt. W. nabbed the young man who opened it, (not the venerable citizen of the day before), and marched him and his bundle of letters to the station house. The young man convinced the officers that he knew nothing of the business of "Clark & Co."—and he was discharged to appear when required. That this firm—which has no real existence—was doing a flourishing business, is shown by the fact that, at this hour, fifty-seven letters were taken, which were turned over to Postmaster James, to be sent to the Dead-Letter Office, where all letters addressed to "Clark & Co." will bring up. It seems that those silly enough to catch at the bait, and say that the enclosed "signature" (see letter above) was theirs, were served with certificates of stock—very pretty certificates they are said to be—and with these a bill of charges for "commissions and expenses." Here is where the profits came from. As it would be some time before the fraud would be found out, "Clark & Co." were doing a flourishing business—as the fools are by no manner of means anything like all dead yet. Indeed, worse than fools—for there were a most lamentably large number, one mail brought 57 of their letters, who, in the hope of getting "a certificate of gold mining stock," were willing to admit the statement to be true, that they had sent money "in the letter from which the inclosed slip was clipped," and thus acted upon what they knew to be a lie, because they expected to make something by it. These persons are not one whit less dishonest than "Clark & Co.," and we think it a great pity that their names could not be made public—though this punishment could hardly be equal to that which each one must receive, when he thoroughly despises himself, for having admitted a lie, in order to allow a gang of scoundrels to swindle him! But, the question will be asked:

HOW DID "CLARK" & CO. GET THE SIGNATURES.

The police authorities think they were procured through the dishonesty of some postmaster. It could hardly be practicable to purloin many thousands of letters from any one Post-office. We think it more likely that they were picked up in junk shops, where the "waste" of hundreds of large establishments is gathered. Unimportant letters are thrown into the waste-basket entire, without even being torn across. A junk-shop is often a well-worked mine for dealers in signatures. As we have stated that there is no such concern as "Clark & Co.," the question will be asked

WHOSE FUNERAL IS THIS?

The young man arrested with the letters, by Captain Williams, said that he was employed by "Elias Brothers."—"Here we are again."—"Now you see it, and now you don't."—It showed the shrewdness of our friend the Postal officer, who, with the same acuteness that allows an Indian to tell the tribe to which another belongs by the prints of his moccasins, saw in the letters and ways, as the frontiersmen say, "fresh sign" enough to induce him to conclude that the tracks of "Clark & Co." were made by the tribe of Elias. And the man that our representative found "representing Clark & Co." at the office, but who did not "represent" worth a cent? *Par nobile fratrum*—they could not be long separated, and wherever the Eliasas are, he will not be found far away. He was then "representing Clark & Co." No doubt he had rather have been at home, teaching his children, if that breed is allowed to be perpetuated, that charming nursery song, "Pat-tee cake, pat-tee cake, baker's man." We have given more space than usual to this one swindle, as it shows how deep-laid and well-guarded are these schemes; and will show those good people who freely ask us to "please investigate, and reply by return mail,"

that these investigations are not so easy as they seem at a distance. Some may wonder why the Elias Brothers were not arrested. Simply because no citizen of the State of New York has made a complaint against them.

The Ailanthus and its Uses.—Prof.

Chas. S. Sargent, Director of the Arnold Arboretum of Harvard University, and also a member of the Mass. State Board of Agriculture, has contributed to the Annual Report of the Secretary of that Board, some most useful "Notes on Tree Planting." The portion of these notes which we have read with the most interest, is that relating to the economical value of the Ailanthus. The *American Agriculturist*, in spite of much ridicule, long ago recommended this tree as one, that for its rapid growth, and its usefulness for fuel and timber, was well deserving the attention of tree-planters. It is true that the tree has one, easily avoided fault, which cannot, in the mind of any sensible person, offset its usefulness. We know of no work in which the reasons for planting the Ailanthus are stated more in full, and forcibly, the opposite side having a fair showing, than in this paper. Prof. S. quotes an example which we some years ago referred to, of a set of furniture made of Ailanthus wood, which can not fail to convince any one of its utility for such work. The paper is by no means devoted exclusively to the Ailanthus; he gives other matters that will be of great use to the increasing numbers of tree-planters in Mass., and of equal value in other parts of New England—indeed we may say to the country at large—for all earnest workers, like Prof. S., "build stronger than they" know.

Heebner's Level Tread Horse-

Power.—A horse-tread power, made by Heebner & Sons, of Lansdale, Pa., possesses a very notable improvement. It is in the raised position of the lower edges of the treads or lags upon which horses move, that this improvement consists. This brings the tread planks in a very easy position for the horses, so that there is little or no strain upon the muscles or tendons, and less fatigue to the animals. This peculiarity belongs specially to this machine, and gives it a prominence amongst other machines, which renders it worthy of more than usual notice.

Pressure at Paris.—The Boomer & Boschert Press Co., of Syracuse, N. Y., whose remarkably powerful presses attracted so much attention at the Centennial, have sent a specimen press, which will no doubt astonish the wine growers, to the Paris Exposition.

"Vegetable Plants" is the title of a work by I. F. Tillinghast, of Tillinghast Bros., Factoryville, Pa. In this work, they give the methods which they have found successful, especially with late cabbage. It has received the commendations of a number of practical growers. The terms on which it may be obtained are given in the advertising columns.

The Treatment of Sick Cattle.—

Probably one half of the letters addressed to the editors, relate to trouble with domestic animals. The present season is one when the greatest care is required to prevent disease in our cattle and other live stock. To prevent, is much better than to cure; and in general it is vastly easier. To prevent disease, it is necessary to know the cause of it, what it is, what symptoms are to be looked for at the outset, and the best method of treating disorder at the very start. A trustworthy *hand-book* giving the proper care of cattle, and the treatment of their diseases, is indispensable to every farmer; yet, a very small proportion of the owners of animals possess any book of the kind. The cost of one of the best of these books would be repaid by the prevention of the loss of one week's milk of a sick cow, the saving of a lamb or young pig, to say nothing of the avoidance of more serious losses. Dadd's "AMERICAN CATTLE DOCTOR," is a standard work of this kind, and will be found of the greatest value in every farmhouse. It is published in two forms; one at \$1.50, and one at \$2.50, sent by mail, by the Orange Judd Co.

Just a Mere Mention.—Pamphlets and

other publications of minor size, but of great intrinsic value, come to us, and we put them aside, hoping for the space in which to give them proper notice, but which never comes. We find, awaiting notice, numerous documents which we must now acknowledge merely by title, or not at all....THE SUGAR BEET in North Carolina, by Prof. A. Ledoux, chemist to the Department of Agriculture of that State. A valuable contribution to our knowledge on an industry which must ultimately become of great importance in every State....THE MENHADEN FISHERY OF MAINE, with reference to its relations to Agriculture, and also as a source of human food. A valuable contribution to all who live on the coast, and fully illustrated by engravings and maps...."A List of the FUNGI found in the vicinity of Boston," by Prof. W. G. Farlow, is not merely of interest to botanists, but to those who would investigate the attacks of fungi upon useful plants....A

similar remark may be made of a paper with the unattractive title of *THE ERYSPHEI*, by Prof. C. E. Bessey, of the Iowa Ag'l. College, in which he describes, and figures some of, the minute fungi that injure our fruit and other trees.... "THE AMERICAN JUNIPERS," "THE OAKS OF THE U. S.," and "THE AMERICAN FIRS," are papers of interest to every nurseryman; and when we say that they are by Doct. Geo. Englemann, of St. Louis, Mo., their scientific value will be admitted by all.... *VENNORS' ALMANAC*, Montreal, Canada, J. Dougal & Sons, is a very full work of its kind, and claims that its weather predictions have been fulfilled to a remarkable degree.... *THE REPORTS* from New Jersey, for 1877, are interesting documents; we have that of the Rutgers Scientific School; the general report of the State Geologist, Prof. Geo. H. Cook, and a special report on the extensive Clay Deposits of the State, which cannot fail to have a high economic value.

Help for the Flower Garden.—We have shown the difference between the modern style of flower gardening, in which the effects—and often most brilliant ones—are produced by massing flowers and foliage; and the older style, in which plants, so to speak, stand on their own merits and are grown as individual specimens, each for its own sake, and without any reference to its effect in a mass. Those who really love flowers, like to read about them, and wish for something more than the mere directions as to their planting and treatment. We know of no work more gratifying in this respect, than Breck's *NEW BOOK OF FLOWERS*. The author, when he had reached an advanced age—about 70, we think—so revised, indeed almost entirely re-wrote his former "Book of Flowers," as to warrant the prefix, "New," to the title. The author's personal experience is told in a charming style, and show how great was the love for flowers which he held through a long, busy, and useful life. We would not imply that the work omits all notice of the use of plants in masses, as it gives sufficient directions for this style of gardening; it is devoted to the description of annuals, biennials, and perennials of all kinds, and of course includes, the "bedding plants;" also ornamental shrubs. Sent from this office by mail for \$1.75.

Protecting Seed against "wire-worms," mice, and other vermin.—"R. W. D.," Flint, Mich., writes that the following method of treating seeds is sent him from England, and he wishes to have it tried in this country and reported upon. It has long been in use in England, as we see it frequently mentioned in the journals. It consists in the use of Red Lead, in the proportion of half a pound to a bushel of seed grain, peas, or other seed. The seed is first moistened with water, and the dry Red Lead sprinkled over it, stirring to secure an even coating. Spread the seed to dry, and then sow.

The Buckeye Mowers and Reapers.—The Buckeye Mowers and Reapers, made by Messrs. Adrians, Platt & Co., of 165 Greenwich St., New York, have long held a very high position in public estimation. While many great and very useful improvements have been made in agricultural machinery during the past few years, the Buckeye machines have kept pace with the foremost in all respects, and have maintained their popularity in spite of the strongest competition. The new Model Mower, wholly of iron and steel, is really a model of beauty, lightness, and effectiveness, and the new reaper has every appliance that can make it desirable and effective in the harvest field.

Special Crops—Special Instructions.—By these we mean crops not included in the usual farm rotation, but which require a different treatment from the ordinary crops, either in their cultivation or their preparation for market. If one farmer happens to make a hit with a crop of this kind, for example with hops, so soon as his success becomes known, hundreds of others, without properly considering if their soil is suited to the culture, or if they can handle the crop when raised, will rush into hop raising blindly, and lose money. Hundreds of others, more cautious than these, will write to us and ask us to give a full account of hop culture, from the planting to the marketing. As with hops, so with several other special crops, such as tobacco, flax, etc. As there is a great deal of detail concerning each of these, and as the processes vary in different parts of the country, it would take more space in the *American Agriculturist* than could be properly devoted to them, as they would be of interest to but a very small portion of the whole number of readers. In view of this, we several years ago adopted the plan of offering prizes for essays by practical growers of these special crops, thus procuring the freshest and most trustworthy information, and the prize essays, with the most important of the others, were published in a pamphlet form, at a low price. These pamphlets, we are sure, contain the best information concerning these special crops, to be found anywhere in print, as they give in detail the practice of experienced growers. They are worth more than they cost, if they

only show one that his land is unfitted or his means are unsuited to the particular culture of which they treat.

If one wishes to know all about Hops, from the planting to the curing, baling, and marketing, let him send for our treatise on *HOP CULTURE*, in which is given the experience of ten different cultivators. Price, 30 cts.

The culture of Tobacco is presented in the same manner, the experience of fourteen growers in one pamphlet on *TOBACCO CULTURE*, which can be had for 25 cts.

Those who think their land suited to ONIONS, can get the story as told by seventeen persons (most of whom have grown the crop all their lives in the best onion districts,) in our *ONION CULTURE*, which is sent for only 20 cts.

The FLAX crop is similarly treated, the essays of a number of experienced growers being collected in our pamphlet on *FLAX CULTURE*, which may be had for 30 cts.

Another special crop, which has recently attracted much attention, is Broom-Corn. Our work on *BROOM-CORN AND BROOMS* not only gives the best cultural directions, but shows how the product is worked up into brooms. As this required a number of engravings, the price is a little higher—50 cts. in paper, and 75 cts. cloth.

The practical character of the above-named works is such, that one who contemplates a trial of either of these special crops, can not afford to do so without first consulting their contents, and learning not only what others have done to attain success, but what to avoid.

Calibre of Shot Guns and Rifles.

—The diameter of the bore of shot-guns is usually indicated by numbers—No. 10 and No. 12 being the sizes most in use. No. 10 is a trifle over 11-fourteenths of an inch, or about 4-fifths of an inch. No. 12 is just three-quarters of an inch inside diameter. The "Forest and Stream" gives the following as the exact measurement: No. 8 is 860-thousandths of an inch; No. 10 is 793-thousandths; No. 12 is 750-thousandths; No. 14 is 715-thousandths; No. 16 is 685-thousandths; No. 18 is 650-thousandths (?); No. 20 is 627-thousandths—the lowest numbers being the largest, and the highest numbers the smallest.—The calibre of rifles, (target, Creedmoor, sporting, army, etc.) is expressed in *hundredths* of an inch. Thus: 50 calibre means 50-100ths, or exactly half an inch. The favorite long-range rifle is 44-100ths of an inch. Target rifles and pistols run all the way down from 44-100ths to 22-100ths, the last being about the size of medium buck-shot.

Horticultural Societies have favored us with their reports, but we can only acknowledge them with our thanks.... The Ag'l. and Hort'l. Society, of Montreal, Canada, send reports of their Fruit Committee, full of valuable information.... The Western N. Y. Hort'l. Society, of which P. Barry is Pres't., hold a meeting, have sensible talk, and get out their report at once, which doubles its value.... The Minnesota Hort'l. Society, send a handsome volume full of matters of interest to all who live in that State or a similar locality.... The Pennsylvania Fruit Growers' Society is doing much good. Its last report is well illustrated; and when we say that Josiah Hoopes is President, it will be understood that things move, one way or another, and that very quick.

An Agricultural Journal in Japan.—Japan is a constant wonder. Having shut itself out from the world so long, it would seem to have devoted this seclusion to preparing itself to accept the best that other countries had to offer, whenever intercourse should be opened. To be sure, it has made some mistakes—but very few. It started an "Agricultural College," which some of our older States and other countries find a great puzzle, and do not know what to do with it, now that they have it. But the Japanese are shrewd enough to distinguish the ornamental from the useful, and in starting an Agricultural Journal, are evidently getting upon the right track. This journal has a handsomely illustrated title page, which, as it is their custom to begin their books "hind side before," is at what we should consider the end of the work. It has, besides the cover, 20 pages of teachings which we have no doubt are excellent; including an illustrated article on the grapevine. We wish our Japanese fellow laborer much success.

Schedules of Prizes, have been received from the N. Y. Hort'l. Society, offering abundant prizes for the spring, fall, and other shows.... The Worcester Co., (Mass.), Hort'l. Society sends a schedule which shows this useful association to be wide-awake.... The Mass. Hort'l. Society, offers only about \$4,500 in their various prizes, and we think shows no sign of collapse.

Percheron and "Percheron-Norman" Horses.—"C. W.," Freeborn Co., Minn. The true Percheron horse is not a large-boned, long-legged, loosely built horse, but many of the half-bred so-called Normans are. There have been many trashy coarse misshapen horses imported into this country as Percherons, which have brought discredit on the race, and an effort is

now making to let these down easy by calling them "Percheron-Normans," a name which signifies only that they are not Percherons. In selecting a horse for breeding, one should not be misled by the large size and great bone. Compactness of frame, fine bone, well knit joints, a clear, bright, intelligent eye, broad forehead, a short round barrel, good chest, and good temper, should be looked to before monstrous size. The breed is well described in "The Percheron Horse," translated from the French, sent from this office, post-paid, for \$1.

Exports of Meat, Butter, and Cheese.

—The exports of meats, live-stock, and dairy products for the period from January 1st to March 31st, 1878, in comparison with last year, are given as follows:

Jan. 1. to Mar. 31, 1878.	Value.	Total for 1877.
Fresh Beef, 12,261,440 lbs.	\$1,112,567	101,971,504 lbs. \$10,047,699
Mutton, 4,355 "	20,837	2,114,240 " 119,560
Sheep, live, 4,069 "	23,425	13,176 63,960
Cattle, live, 2,174 "	260,825	20,057 2,987,740
Horses, 479 "	71,550	4,668 750,220
Mules, 1,013 "	161,189	1,670 283,900
Hogs, live, 765,000 "	39,599	284,000 " 17,040
and dressed, 17,619,839 "		
Butter, 118,425,531 "		same time last year, 13,566,110 lbs.
Cheese, 118,425,531 "		82,837,668 "

While the exports of meat and live-stock, with the exception of sheep and mules, have decreased somewhat, the very large increase in dairy products is noteworthy. It is of interest also to note here the growth of shipments by way of New Orleans, of Western products, as shown by the following figures, viz.:

Shipments of Corn from N. Orleans, Sept. 1, '77, to Mar. 1, '78
 1877... 789,136 bushels
 1878... 3,709,522 } Increase 1878, 2,926,386 bushels.

The shipments of wheat from this port, also show a marked increase the present year.

A Poland-China Record.—A meeting of breeders of Poland-China Swine in the United States and Canada, was held at Cedar Rapids, Iowa, January 23, 1878, at which it was agreed that a record, for registering the pedigrees of this breed of swine, has become a necessity. For the purpose of publishing such a record, an incorporated company was formed, every breeder present becoming a stockholder. The following officers were elected: President, W. P. Sisson; Vice Presidents, B. F. Dorsey, Jos. Morton, Wm. A. Macy, S. A. Clark; Secretary, J. T. Mitchell; Treasurer, J. C. Traer. A standard of entry was agreed upon, and an Executive Committee appointed, who will pass upon all pedigrees. A report of the proceedings can be obtained of the Secretary, at Cedar Rapids, Iowa, for 15 cents.

The N. Y. Horticultural Society's monthly meeting, held on March 5th, was by far the best attended of any since the organization of the Society. Besides many professional gardeners, quite a number of amateurs were present. The display of Hyacinths in pots was unusually fine. The first premium was awarded to Mr. Rohers, florist, of Jersey City. He was followed closely by James Murkland, of 12 Cortlandt street, whose plants, considering that they were grown in an ordinary sitting-room, were highly creditable. A dozen fine specimens of Double Geraniums, exhibited by Mr. Reynolds, of Flatbush, L. I., were awarded a special premium. George Such, of South Amboy, carried off the \$20 premium for cut-flowers, offered by the President of the Society. Fine specimens of Cyclamen and "Cornelia Cook" Roses, sent from Mr. Jones, gardener, at Madison, N. J., took a special premium. An interesting lecture, given by Mr. Boileau, on training and pruning Pear-trees, was received with marked attention. A paper from Dr. John A. Warder, of Ohio, suggesting a "Governmental Bureau of Forestry," was received rather coldly, the Society evidently having the idea that there are already about enough of such Government Bureaus. Henry Ward Beecher, of Brooklyn, and Thomas Meehan, of Germantown, Pa., were elected honorary members.

For Boys and Girls, and other players of games.—When Aunt Sue gets hold of a pleasing game, she naturally hastens to tell others about it; hence, when a lady showed her the game of "Word Making," given on page 145, she at once sent it for the Boys and Girls' Department. Having somehow got the impression that "Logomachy" was one of the names of the game, she gave that as one that you might use, if you liked it better than "Word Making." She has, since the article was printed, (that part of the paper being on a separate sheet, and printed a week or more before this), discovered that "Logomachy" belongs to a different game. It is a name for a game invented by a gentleman in Ohio—Mr. F. A. Wright—and one which we have no right to use for a different one. Of course neither Aunt Sue nor ourselves, knew of this, when the article was put in type, and a part of the sheets were printed before the accident was discovered. The mistake has been remedied in a part of the edition; those of you who may get a paper in which "Logomachy" is given as one of the names of the game,

are requested to draw a pencil through that word, to remind you that it belongs to a very different game. But good things are often hit upon by more than one person, and it now appears that the game described by Aunt Sue, though quite unlike Mr. Wright's, is similar to one offered for sale by C. E. Hammett, Jr., a well known bookseller, of Newport, R. I., who furnishes the boxes of letters, with printed directions for playing the game, which he will furnish by mail, post-paid, at 27 cents. We may add that we hardly know of any other way in which this small sum will afford so much amusement, as besides the game referred to, the same letters may be used for various other games described by Aunt Sue.

Percheron Horses.—A meeting of importers and breeders of Norman or Percheron horses, was held at Peoria, Ill., on February 14th last. The chief object of the meeting was the change of name of the Association of breeders and importers of Norman horses, and the addition of the word Percheron before the word Norman. This object was accomplished. The stud book will now be called "Percheron-Norman." A motion to the effect that the Percheron and Norman horses were one and the same breed, was laid on the table. This is well, as all the "resolving" would hardly change the fact that they are different horses in many respects. Only imported horses, native full bloods, and animals having five pure crosses, can now be admitted to the stud book.

Scurvy in Poultry.—"A. C.," St. Mary's River, Ga., sends the following account of a fatal disease affecting fowls in his locality, which he calls "warts." "The warts begin to show themselves with warm weather—(here, our climate is nine months summer, and three of spring), generally about the head and neck, working towards the mouth and around the bill. They resemble the human 'small-pox.' The pustules are filled with yellow-colored matter. If the warts get into the mouth, the bird is choked, as the tongue and throat swell up, as in diphtheria. As remedies, sulphur, gas-tar, kerosene, etc., have been tried in turn, and failed. The birds, as well as chicks, are attacked. Sometimes the whole body is affected, when the feathers fall off. Turkeys, likewise, have the disease, but 'water-fowl,' such as geese and ducks, in the same yard, are perfectly free from it."—The disease is scurvy. It is, fortunately, rare, because, when it attacks a flock, it generally destroys the whole, unless measures are taken to stop it. These are, to administer to each bird ten grains of sulphur and one grain of calomel, every alternate day; and to apply to the diseased parts an ointment, made of one ounce of sweet oil, mixed with one-third of an ounce each of sulphur and turmeric. The disease is in the blood, and is not warts, by any means. To prevent its spreading, give chopped fresh vegetables and boiled oatmeal mush to the other fowls; and put in the drinking water enough Aromatic Sulphuric Acid (Elixir of Vitriol) to make it decidedly sour to the taste. Also, separate the sick birds from the well.

The Pip in Poultry.—"W. T. W.," Dutchess Co., N. Y. Poultry are sometimes troubled with a disease known as "pip." This is inflammation of the tongue and mouth, with the growth of a horny scale on the point of the tongue, which prevents the fowls from feeding. Give each fowl a pinch of powdered chlorate of potash, dropping it into the throat and upon the tongue, and remove the scale with the point of a penknife.

Fresh Manure bad for Potatoes.—"J. H. T.," Palmyra, O. Fresh manure is hurtful to potatoes. This crop needs old well-rotted manure, or the tubers are apt to be scabby, and to be infested with white worms. Fresh manure may be used for corn without any ill effects. The corn rather likes it. There are no potatoes so clean and free from blemish, as those grown with the artificial fertilizers.

To get Land under Grass quickly.—"A. M. D.," Portsmouth, Ohio. After a wet piece of land has been underdrained, it may be best seeded by plowing and sowing with oats rather thinly. Oats succeed well upon cold moist ground, and upon a sod, and if there are no more than 2 bushels of seed per acre used, the grass seed will take very well with this crop. A mixture of 4 quarts of timothy, a bushel of red-top, and a bushel of blue-grass per acre, would be preferable.

Catalogues of Dealers.—A list of the catalogues received since those acknowledged last month will be found on page 153. This, together with the remarkable variety of advertisements, can not fail to interest all intending to purchase.

Culture of Potatoes.—"H. T.," Portage Co., Ohio. For general planting, now that the potato-beetle is with us as a permanent companion, the early varieties of potatoes will be preferable. Of these

the "Early Rose" is yet a standard sort. The "Snowflake" is one of the favorite new varieties for field culture. "Early Vermont" has been found to succeed in some localities, and is worth trial, and there are several still newer early kinds that promise to be valuable. Late potatoes, in the East at least, have mostly succumbed to the beetle, and have been an almost total loss, or have cost more to save than they have been worth. Drill culture is undoubtedly the most profitable. With drills 24 to 27 inches apart for the early kinds, the seed may be dropped in single sets 9 inches apart, or two sets in a place, 18 inches apart. The earlier the ground is prepared, and the sooner afterwards the seed is planted, the more forward will be the crop, and the better able to resist the beetle. Last year the earliest potatoes suffered very little, and Paris Green could not save the late ones.

The Ground Nut, *Apios tuberosa*, was figured and described in January, 1877. It was there stated that the root was one of the many things offered several years ago as a substitute for potatoes. We had not then made a trial of the tuberous root, having never seen any large enough. Last fall, Mr. E. S. Miller, of Suffolk Co., (L. I.), N. Y., sent us a fine lot for planting; there were a few among them about as large as a black walnut—very black-coated and unpromising looking things they were. We had these boiled, and though when served their appearance was by no means attractive, we found them really palatable; quite dry and somewhat sweetish, and with a flavor somewhat between that of a sweet potato and a boiled chestnut. We do not know how long it takes to grow a root like the largest of these, but when grown, and one has a plenty of them, it would take him a long time to starve to death.

To Rid Hogs of Lice.—"W. E. G.," Henrico Co., Va. To destroy lice upon hogs, rub well into the bristles, along the spine, on the brisket, and beneath the arms and thighs, a mixture of lard and sulphur well rubbed together.

Diuresis in a Heifer.—"D. H. H.," Success, L. I. Diuresis, or excessive secretion of urine, may be caused by anything that will unduly stimulate the kidneys. Musty hay, smutty corn-fodder, mouldy meal, bran, or other food, or acrid weeds in the hay, all have this effect. The remedy is to seek out and avoid the cause, and to give mucilaginous drinks, such as oat-meal or linseed-gruel, with a teaspoonful of powdered Peruvian bark, and as much powdered sulphate of iron, daily.

Growing Beans.—"W. S. C.," Fulton Co., Pa. Beans are a valuable crop, and give very little trouble. The most troublesome part of their culture is to preserve them from rain after they are pulled, so as to keep their color perfectly. When damaged by wet, they become stained, and reduced in value. The crop could very well be added to the ordinary rotation—for instance, after oats—as they can be got out of the way in time for sowing wheat, and wheat succeeds better after beans than after oats. Besides there is one more cultivated crop in the rotation, and the wheat would be cleaner.

Belted Cattle.—We have numerous inquiries from many parts of the country for the belted cattle, which were illustrated in the *Agriculturist* for Dec. last. A reply will be found in the advertising columns.

The best Stock for a Milk Dairy.—"C. M. W.," Orange County, N. Y. The best cows for a milk dairy are grade Shorthorns. They milk plentifully, giving rich, high-flavored milk, and the cream does not rise rapidly upon it. This renders the milk most suitable for shipping to a city or town market. By good feeding, cows of this kind are kept in good flesh, and when failing in milk, they fatten with rapidity. We cannot see how a milk dairyman can afford to raise calves. Profit is only made from milk, and a dry cow soon "eats her head off." A good supply of dairy cows is to be found in Southern N. Y. and Northern Pa., in the region of the head waters of the Delaware and Susquehanna rivers. A good class of stock is kept there bred to supply purchasers.

"Plain Facts About Florida" is the title of a pamphlet by Geo. W. Dow, Ferdinandina, Fla. We are rather careful in noticing works about Florida—at least those written with a view to induce emigration thither. The impression prevails, as our correspondence shows, that the advantages of the State have been overpraised, and that many persons have been, by glowing descriptions, induced to go there, who would, if they only could, gladly get home again. This is true of all emigration fevers. We do not believe in such fevers, and our advice has always been, with reference not especially to Florida, but to any other State—Don't move to or locate anywhere, without first visiting the place, and seeing the land. Those, whether individuals or companies, who have land to sell, will present all the at-

tractions of the locality, be it in Florida or Alaska, and utterly ignore the drawbacks, and will continue to do so, as long as human nature remains as it is. We think that this little book of "Plain Facts" is very moderate, especially when we read on p. 13, "Mosquitoes and sand-flies are an incumbrance that Florida will never be free from," and that, "Fever and ague prevail in some localities at certain seasons." Evidently the author has eyes to see both sides, and he will prove in the end a better friend to the State than those who represent it is a paradise, which one has only to reach to enjoy and prosper. Sent from this office, post-paid, for 25 cents.

Basket Items continued on page 152.

Exports of Agricultural Produce.

The exports of agricultural products for 1877, were as follows:

Breadstuffs, (which include all kinds of grain).....	\$140,068,087
Cotton.....	158,258,286
Oil-cakes.....	4,276,050
Provisions.....	109,723,172
Seeds.....	2,565,733
Tobacco.....	28,497,479
Fruits.....	1,836,918
Total.....	\$445,225,725

The total exports during the year were \$671,632,366. The products of agriculture furnished, therefore, more than two-thirds of the whole of our foreign exports. This is a fair test of the relative importance of the agricultural interest, as compared with other national industries. When we compare the proportionate demands made by other industries upon the Government for recognition and assistance, with those afforded to agriculture, a very conspicuous inequality is apparent to the disadvantage of the latter. Farmers are permitted to get along as they can without help, and in spite of some hindrances, while other industrial classes clamor for help and get it. If we add to the above figures the vast amount of inland traffic supplied by agriculture, the comparison would be very much more in its favor in one way, and its disadvantage in that pointed out.

More About Farm Experiments.

The following is in addition to the general article, with the above title, given last month, on page 86. An editorial, page 131, gives a summary general view of the object and aims of these experiments; and Prof. Atwater discusses the subject on page 130. It will be noticed that some important additions are made to the "extras," while the regular Set A is unchanged:

Experimental Fertilizers.

Bag No.	MATERIALS.			Price per bag.
	Kind.	A-mount.	Valuable Ingredients.	
SET A.				
I.	Nitrate of Soda.	20 lbs	Nitrogen.	\$ ct
II.	Dissolved Bone-Black.	30 "	Phos. Acid	1.00
III.	Muriate of Potash.	20 "	Potash.	.60
IV.	{ Nitrate of Soda.	15 "	{ Nitrogen.	1.40
	{ Dissolved Bone-Black.	30 "	{ Phos. Acid }	
V.	{ Dissolved Bone-Black.	30 "	{ Phos. Acid }	1.25
	{ Muriate of Potash.	20 "	{ Potash.	
VI.	{ Nitrate of Soda.	15 "	{ Nitrogen.	1.90
	{ Dissolved Bone-Black.	30 "	{ Phos. Acid }	
	{ Muriate of Potash.	20 "	{ Potash.	
VII.	Plaster.	20 "	—	.15
PRICE OF SET A				\$7.00
EXTRAS.				
Ia.	Sulphate of Ammonia.	15 lbs	Nitrogen.	.95
Ib.	Dried Blood.	25 "	Nitrogen.	.80
IIIa.	Sulphate of Potash.	20 "	Potash.	.85
IIIb.	Kainit.	30 "	Potash, &c.	.35
IVa.	{ Dried Blood.	20 "	{ Nitrogen.	1.25
	{ Dissolved Bone-Black.	30 "	{ Phos. Acid }	
VIII.	Pure Bone-Meal.	50 "	{ Nitrogen.	1.25
			{ Phos. Acid }	
IX.	Fine Bone Dissolved.	50 "	{ Nitrogen.	1.25
			{ Phos. Acid }	
X.	Dry Ground-Fish.	50 "	{ Nitrogen.	1.20
			{ Phos. Acid }	
XI.	No. 1 Peruvian Guano.	40 "	{ Nitrogen.	1.40
			{ Phos. Acid }	
			Potash.	
XII.	Rec. Guano, "Oneco,"	50 "	{ Nitrogen.	1.50
			{ Phos. Acid }	
			Potash.	
XIII.	{ Nitrate of Soda.	15 "	{ Nitrogen.	1.30
	{ Muriate of Potash.	20 "	{ Potash.	

Each article will be put up in a small bag, numbered I., II., III., Ia., etc., as above. Nos. I. to VII. will be put in

a large bag, as "Set A." The price of "Set A" is \$7. The small bags will be packed together in large bags or boxes for shipping. To last month's list of extras, we have added Kainit, IIIb, and rectified Peruvian Guano, brand "Oneco," and thus include samples of all the more important kind of artificial fertilizers in the markets. The "Oneco" brand of guano differs in having a third as much nitrogen, and a good deal more phosphoric acid and potash, than the "Standard." No. IVa is a high-grade "ammoniated superphosphate." The pamphlet, with explanations and directions, which will accompany each lot sent, is prepared especially to tell what the farmers ought to know about the fertilizers and the experiments, and will describe at length the experience of farmers last season with similar ones. Blanks will also be sent for recording and reporting results.

Bees Notes for April.

BY L. C. ROOT, MOHAWK, N. Y.

In many locations bees, which have been wintered indoors, should be placed upon their summer stands this month. I can not too strongly warn persons against the common practice of removing bees from their winter quarters too early in our northern latitude. Unless the spring is unusually early, do not set them out until the first of May. The blossoming of the Soft Maple tree is a good indication of the proper time for each locality.

I am strongly opposed to the practice, so often advocated, of setting bees upon their summer stands before natural forage appears, and feeding to stimulate breeding, before the weather is sufficiently warm. Until this practice is discontinued, we shall be sure to suffer by what is known as "spring dwindling."

Many swarms of bees are placed upon their summer stands on April 1st, in fine condition, and before May 1st become so much reduced, that many of them never recover. When bees are taken out of the cellar, all ventilation should be closed, except at the entrance, and that should be contracted. Too much pains can not be taken to economize the heat. All openings in the top of the hives should be kept well closed. If movable comb hives are used, all combs, except those occupied by bees, should be removed, and a close-fitting division board be placed at the side of the combs left in the hive, thus contracting the space in the brood chamber in proportion to the size of the swarm. These directions apply also to hives that have been wintered out-of-doors.

The Parasites of the Honey Bee.

I have investigated this subject for two years past, and during the past winter have given it special attention. While examining the dust which is found upon the bottom-board under a swarm when wintering well, I discovered numerous minute insects. I have so far observed six different forms, but have not become sufficiently acquainted with them to determine whether or not they are all distinct. I have studied their habits, and the circumstances under which they are found, to such an extent, that I feel warranted in the belief that much of the uneasiness of bees in winter-quarters, and consequent poor success in wintering, is largely due to the presence of these parasites. My observations also indicate that the immature young bees which are often thrown from the hives during spring and summer, sometimes in large numbers, have been destroyed by these insects. These facts lead us very naturally to an explanation of what has been the greatest mystery and obstacle to bee keeping, viz., foul brood. I am decidedly of the opinion that both this plague, and its almost total eradication, are due to the operations of different varieties of parasites. Our experience with cabbage and currant worms, potato beetles, and other pests, whose devastations are sensibly checked by their respective parasites, corroborates this view. I find, upon a study of Packard upon "Our Common Insects," that the subject of parasites on honey bees has received considerable attention abroad, and that the cause of foul brood is therein attributed to the feeding of these parasitic insects upon the immature bees.

Weight of Swarms.

The amount of honey consumed during February, by the four swarms mentioned in previous months, is as follows:—No. 1, 1½ lbs.; No. 2, 1¼ lbs.; No. 3, 3¼ lbs.; No. 4, (the swarm kept out doors), 4¼ lbs.

Questions and Answers.

INTRODUCING QUEENS.—"When shall I introduce Italian queens into black stocks?"....The best time is when swarms are being increased. Make swarms artificially, and introduce the queens to such swarms. If the entire apiary is to be Italianized, the queens in the old swarms should be changed later in the season.

LEAVING SWARMS QUEENLESS.—"Is leaving the swarm queenless 7 days in June, compensated for by the Italians working on red clover?"....No. It is injudicious to deprive a swarm of a queen for this length of time at that season. With practice, queens may be introduced at any time during the working season, without depriving the

swarm of a queen, except for a short time. When all circumstances are favorable, one queen may be removed and another replaced at the same time.

ADDING COMBS FOR BROOD REARING.—I would add combs to the center of the brood nest, and allow bees free access to them, and not cover any part, as suggested.

FEEDING SUGAR.—"Is not brown sugar cheaper than 'coffee A,' for wax making and brood rearing?"...If pure, I prefer coffee A.

Science Applied to Farming.—XL.

Plans for Farm Experiments with Fertilizers.

"These experiments, it is true, are not easy; still they are within the power of every thinking husbandman. He who accomplishes but one, of however limited application, and takes care to report it faithfully, advances the science, and, consequently, the practice of agriculture, and acquires thereby a right to the gratitude of his fellows, and of those who come after. To make many such is beyond the power of most individuals, and cannot, therefore, be expected. The first care of all societies formed for the improvement of our science, should be to prepare the forms of such experiments, and to distribute the execution of these among their members.—ALBRECHT THAER, *Principles of Rational Agriculture.*"

I give herewith the promised plans for experiments, dividing them, for convenience, in three classes, some extremely simple, inexpensive, and easy; others more complicated and costly, but all useful.*

1.—Experiments Especially for Testing Soils.

Suppose a farmer wishes to ask his soil: "What fertilizing materials do you most need in order to bring me crops?" Or, to state it more fully: "Of the ingredients of plant-food which my crops must have, what ones can you furnish from your own stores, and what ones must I give you to make up the deficiencies in your supply?"—For this, I suggest an experiment, in which the three ingredients of plant-food most important from the agricultural point of view, viz.: Phosphoric acid, Nitrogen, and Potash will be used, each by itself; two by two, and all three together.

SET A.

Bag No.	Kind.	Amount.	Valuable Ingredients.
I.	Nitrate of Soda.....	20	lbs. Nitrogen.
II.	Dissolved Bone-Black.....	30	" Phos. Acid.
III.	Muriate of Potash.....	20	" Potash.
IV.	{ Nitrate of Soda.....15	{	{ Nitrogen.
	{ Dissolved Bone-Black.....30	{	{ Phos. Acid.
V.	{ Dissolved Bone-Black.....30	{	{ Phos. Acid.
	{ Muriate of Potash.....20	{	{ Potash.
VI.	{ Nitrate of Soda.....15	{	{ Nitrogen.
	{ Dissolved Bone-Black.....30	{	{ Phos. Acid.
	{ Muriate of Potash.....20	{	{ Potash.
VII.	Plaster.....	20	"

That is to say, on one plot a complete fertilizer would be used, contained in bag No. VI.; on another, the same, without nitrogen (bag V.); from a third, potash would be omitted; while on others, the ingredients would be applied each by itself. Nitrate of soda is chosen as the best single material, except, possibly, sulphate of ammonia which could be used also, to test the specific effect of nitrogen; and because nitrate of soda, like sulphate of ammonia, is a thing that our farmers ought to become better acquainted with. For phosphoric acid (soluble), dissolved bone-black, and for potash, the "muriate" is selected, as these are among the cheapest and best forms in which the respective ingredients can be bought.

The seven bags of Set A, for one-tenth of an acre each, will, with one other fertilizer, and two unmanured plots, suffice for an acre. For the other fertilizer, I would suggest yard-manure, unless "Extra" No. XIII., nitrogen and potash, with no phosphoric acid, can be bought. This would have been put in Set A but for the cost. Set A, with No. XIII., makes the same series as is recommended by Wolff "as a test, both of the needs of the soil, and of the light to which the yield at harvest can be raised, under existing conditions." He says:

"It is of the greatest importance to the farmer to find out which of the more important ingredients of plant-food his soil, in its actual condition, fails to supply in

*See page 129, for list of fertilizers, cost, etc. Detailed explanations of points farmers will want to know about, with directions for making the experiments, will accompany each lot sent out.—Ed.]

sufficient quantity for the production of the largest possible crops, and which, when directly added, would therefore exercise an especially favorable and profitable influence.—This can be done, practically, only by properly conducted fertilizing experiments....The trials should be made on land which is exhausted, in the agricultural sense of the word, and would, in ordinary practice, have been again dressed with stable-manure."

In addition to the regular set, it would be well to try several "extras," particularly Peruvian guano and fish, and with them, other fertilizing materials. The value of Mr. Bartholemew's experiment, described in February, was very much increased by the trials with ashes, leached and dry, and the manures produced on the farm.

The "Natural Strength" of the Soil to be Tested.

The soil is not like a cistern, which we may pump dry, and must then fill up again before it can be of use. It is rather like a pond, which may be drained very low, but whose supply is being continually renewed. This continual re-supply of plant-food is the most important feature of its "natural strength." The natural strength of most of our soils suffices only for very small crops. The crop can not rise above the level of the lowest ingredient in the food supply. The proper use of commercial fertilizers, like guano, phosphates, potash, salts, and the like, is to fill up the gaps. In a soil that has a store of available plant-food, accumulated by natural processes, or left over from previous manuring, the specific effect of the experimental fertilizers will not be so clearly marked, and we shall not be able to tell so well what we may expect from it.

2.—Experiments to Test Especially the Action of Fertilizers.

Some may wish an answer to such a question as this: "Of the different fertilizers to be had in the markets, what ones, if any, can I use to advantage, and which will be most profitable?" For this purpose, Set A entire, or Nos. I., II., III., and VII., separately, any of the extras, and other articles can be used. But where calculations in dollars and cents are wanted, the utmost care should be taken to make the experiments accurate.

I wish to call especial attention to nitrate of soda, Peruvian guano, fish, bone, and potash salts. Nitrate of soda furnishes nitrogen, about 16 per cent, in form ready for immediate use by the plant. It is excellent for a top-dressing for grass and grain, especially in spring to bring up backward winter wheat, or encourage the growth of grass on pastures, meadows, and lawns. It is used in immense quantities in Europe. A gentleman whom I happen to know as one of the best farmers in Germany, says that he considers it "a sin to try to grow oats without nitrate of soda." Sulphate of ammonia is similar in action to nitrate of soda, and less exposed to loss by leaching out of the soil, but, on the whole, I think no better, if as good, in its practical effects.

Peruvian guanos, as now sold, taking into account composition, quality, and price, are the cheapest class of fertilizers in the market. There are different grades, furnishing nitrogen, phosphoric acid, and potash, in varying proportions, and adapted to the varying wants of different soils and crops. Fish rivals guano in cheapness of nitrogen and phosphoric acid, and, when rightly prepared, is often preferable to anything else. I hope that numbers of experimenters will try Peruvian guano and fish.

Fertilizers for Special Crops.

Hundreds of farmers near cities and villages, grow potatoes, onions, and other vegetables, for market. Very often the addition of some special fertilizer, like potash salts, to the other manures used, will increase the crops wonderfully. A gentleman recently told me of a case in point from his own experience. A near neighbor and himself were raising onions last season on similar soil. Each one of them treated his crops in the same way, except that he used sulphate of potash, his neighbor did not, and he got several hundred bushels more of onions on the same area. A few dollars invested in the potash salts, increased the market value of his onion crop by \$200 or \$300. Cases like

this are very common with potatoes and other vegetables. I would recommend experiments on such crops with potash salts, either with Sulphate of Potash, (1a); "Muriate," (1); and Kainit, (1b), side by side, to test the action of each, or with the Sulphate alone. Similar experiments will often be useful on grass, grain, corn, and clover. For these the "Muriate" (1) may do as well as the Sulphate, (1a), and is cheaper. In like manner, bone, raw and superphosphated, Nos. VIII. and IX., can be tried wherever the farmer may desire.

These experiments, whose object is more to test the fertilizers than the soil, may be made on soils in better condition than would be appropriate for those of the first class for testing the soils. But it must be borne in mind that in no experiment will the first year's crop tell the whole story; that the after-effects are important; that the crops of succeeding years will have something to say, and perhaps something different. Indeed, this is true of all the experiments, and to make them complete they should be continued through a series of years and crops. At the same time, a good deal may be learned from the first season's results, and I think those who do them rightly, will be more ready for the repetitions than they were for the first trials.

Experiments for Obtaining More General Information.

The inferences from field experiments are of general value in proportion as the questions are specific, the plans appropriate, and the trials made under known and specified conditions, in varying circumstances, with different crops, and through series of years. To the large amount of useful information obtained from field experiments, a great deal more can be added. For instance, corn is one of our most important crops, and is becoming more and more so in Eastern and Southern States. But farmers, in those States, must depend largely upon artificial fertilizers for growing corn. What materials and mixtures can they best use? It is, of course, foolish to talk of prescriptions to fit all cases, but nobody knows now just what will be best for any case. The fact is, that the knowledge we have of the feeding capacities of corn, its power to obtain its food from soil and air, how different fertilizers and other circumstances affect it, knowledge of the definite sort that comes from accurate experimenting, is extremely limited. But by a series of experiments carried out in a number of places, with uniform manuring, seed, and tillage, and accurate descriptions of soil, weather, and other conditions, we might learn a good deal that would be valuable. Take, for instance, as the main question, the nitrogen supply; how much capacity corn has to get it from the soil, and how it will best be supplied in manures. We might use (1.) the fertilizers of Set A, which would give a test of the soil, and to some extent of the fertilizers also. Then (2.) to test the effects of nitrogen alone in different combinations, apply, along side of I, Nitrate of Soda, 1a, Sulphate of Ammonia, and 1b, Dried Blood. To test the action of nitrogen with other fertilizers, we could start with the mineral manures, V, (phosphoric acid, sulphuric acid lime, and potash) as a basis; and (3) try the effect of varying quantities of nitrogen by adding to these nitrate of soda, at the rate of 100 lbs., 200 lbs., and 400 lbs., per acre, on successive plots; and (4.) the effects of nitrogen in different combinations by adding sulphate of ammonia, and dried blood on others; and using Peruvian guano, and fish, each with potash salts, and finally stable-manure on still other plots. This would make, with three unmanured plots, say twenty in all, for which the fertilizers might cost as many dollars, an experiment but little more difficult or costly than farmers often make, and one that educational institutions and public-spirited individuals might unite with most valuable results. Of course similar plans could be devised for other crops, as is being done to considerable extent of late by the European Experiment Stations.

I make this proposal with the more assurance, because several professors and farm superintendents in our agricultural colleges, and public-spirited farmers, have expressed to me their desire to co-operate in such experiments. It was, indeed,

through the solicitation of one of the institutions referred to, that I was led to bestow especial thought to the subject. I should be pleased to correspond with any who may be interested to join in such an enterprise.

W. O. ATWATER,
Wesleyan University, Middletown, Conn.

Plants May Thrive on a Meat Diet.

BY PROF. ASA GRAY.

After it was ascertained that Sundews and Venus' Fly-traps digested insects as well as caught them, it was still a question if it did them any good. We ourselves see no difference between supplying combined nitrogen to the roots in the form of manure, and to the leaves of such as are capable of imbibing it, in the form of fresh animal matter. And we could never be brought to believe that such peculiar organs and peculiar actions went for nothing, or served no purpose useful to the plant itself. Such an idea would, to our thinking, border on the atheistical. But some very good people were free to express such an opinion; and some made what they called experiments or observations; from which they concluded that such plants fed with insects, or with bits of meat, or allowed to help themselves to the former, were no more vigorous than those from which every thing of this sort was excluded.

Now Mr. Darwin's son, Francis, has put this to the test by careful and decisive experiments. At the beginning of summer, he put 200 plants of common Round-leaved Sundew (*Drosera rotundifolia*) into wet moss on soup plates, divided each plate into two halves by a partition, fed the leaves of the one-half every few days with little bits of meat; left those of the other half without any, and, covering all with gauze, prevented them indulging in the capture of insects. Before long it was clear that the fed plants were profiting by their meat diet. That is, they were perceptibly more vigorous in growth and of a better color; and in time they produced more flower-stems, and larger ones, as well as more leaves. And, what is still more decisive, they bore a larger crop of seeds, and heavier seeds. The exact result as to the crop is recorded in the following table, where the numbers and weights are put into the form of percentage. The first column of figures is from the starved; the second from the fed plants:

	No Meat.	Meat Diet.
Total number of flower-stems.....	100	: 121.5
Sum of the weights of these.....	100	: 164.9
Total weight of these.....	100	: 231.9
Total number of pods produced.....	100	: 194.4
Average number of seed per pod....	100	: 122.7
Average weight per seed.....	100	: 157.3
Total calculated number of seeds produced.....	100	: 241.5
Total weight of seeds produced.....	100	: 379.7

As it is to the seed that assimilated nitrogen mainly and finally goes, being "put where it will do most good," these last figures are most significant; and the bearings of these facts upon vegetable physiology are noteworthy. Anyhow, it is clear that such plants do not catch flies for naught, or out of mere naughtiness.

Those Important Farm Experiments.

Every farmer, who possibly can, should take a hand in the important experiments announced last month, and further described now, on page 130. They may be worth hundreds of dollars hereafter to every one who tries them. The actual outlay need not be over \$7 for fertilizers, with a trifle more for freight, while a considerable proportion of this, if not the whole, or more than the whole, will be quite likely to be returned the present year, by increase of crops on the experimental acre. Let us re-state the proposal here as plainly as may be:

Naturally poor soils, and those which have been cultivated or worn, have lost one or more elements of fertility. We can not see what is missing, and an analysis of the soil will not inform us definitely. It is now pretty generally agreed that the lacking element is one, or more, of the following: POTASH,

or NITROGEN, or PHOSPHORIC ACID, or LIME, or, perhaps, SULPHURIC ACID. One soil or crop differs from another in what it lacks. Barn-yard manure supplies all the elements. So do some of the compound manufactured fertilizers; but there is seldom enough yard-manure on any farm for its necessities or its best profits.—We may buy a compound fertilizer, having equal parts (in cost) of four of the important elements; yet if only one of these is needed by the soil, we throw away \$3 out of every \$4 paid, besides the labor and cost of handling. Millions of dollars have been lost by our farmers

Fig. 2.—PLAN OF CELLAR.—(See page 132.)

in this way; millions more by buying and using fertilizers that, however good of their kind, did not happen to contain just the element wanted, and other millions by not getting the article paid for.

THE REMEDY.

The plan, in brief, is this: The farmer selects an acre of land as nearly as possible like the rest of his soil. This is to be laid out in ten long plots. Upon some of these plots are to be applied certain single fertilizers; on others, two of them or three of them together. Two or three plots among the others are to have no fertilizers applied. Now, across these plots are planted, or sown, strips of corn, potatoes, grain, etc., the crops most raised by the experimenter, and, therefore, most desirable to have tested.

It will at once be seen that by watching these crops where they cross the various fertilizers, we will get a direct answer as to what that soil needs for each crop put upon it. For example, if the corn on the potashed plot is just as good as on the plot having potash, phosphoric acid, and nitrogen, we shall know that it is a great waste of money to buy costly phosphates and nitrates for such a soil and such a crop. If any one or two fertilizers show a good profit in their use, as some of them doubtless will, we shall know what to use next year and thereafter on a larger scale.

The great advantages of the scheme, as proposed, are these: 1st. The fertilizers sent out are all to be tested for quality, purity, percentage of each element, etc., by Prof. ATWATER.—2d. They are to each be weighed, and sent in separate bags, ready to be used on a tenth of an acre—a plot 16 rods by 1 rod, or otherwise. 3d. The fertilizers will be supplied at a price just to cover cost of preparation, bags, etc. No one is to make anything out of it. (This Journal will make a loss in trouble, etc., but a gain in the general information

that will thus be gathered by its readers and the public.)—4th. Pamphlets prepared by Prof. ATWATER will be sent with each parcel, giving full and specific directions for making the experiments, and ascertaining the results.—Finally: as before stated, this project carries an "Agricultural Experi-

ment Station" to each farm where these experiments are tried, and supplies to the owner the information he wants, at small cost, if any—perhaps a profit. Neighboring farmers having very similar soils will also be benefited.

hall, parlor, kitchen, pantry, and to the stairs. [We suppose this room is to be warmed by a stove, having pipe entering the chimney shown in the parlor only. The arrangement for chimney for the kitchen was described last month.—Ed.] The Kitchen is commodious and pleasant; has three windows, an outside rear entrance, and adjoins the dining-room, pantry, and bed-room. The Pantry is sufficiently large and convenient to answer the requirements of both dining-room and kitchen. It has a small window, and is thoroughly shelved. The Bed-room opens directly from the kitchen. Its purpose in the partial erection (as shown last month) may be changed in the completed building here described, by making it an auxiliary of the kitchen for the coarser work; or, if needed, it may still be used as a bed-room for help....**Second Story,** (fig. 4).—Height of ceiling, 7 feet. There is a hall, two chambers, two bed-rooms, and two closets in this story, and no waste room. The Hall is just large enough for convenience. The Chambers are of ample dimensions, with a chimney between them, admitting the use of stoves when required....**Construction.**—The Foundation for the main house is of broken stone, and mortar, showing 3 feet above ground, neatly pointed where exposed to sight. The Wing is supported on piers, as described last month. Girders, (shown on the cellar plan by dotted lines), supported on strong posts, carry the central portions of the building. The shortness of the spans between bearings, allows very light floor beams. It is, however, important that the beams should be bridged to secure uniformity of strength, and prevent vibrations. The Frame is constructed in the usual manner—all the ties, girts, and headers, being "framed in." The inclosing is sufficiently indicated in the estimate. The front

quarter circle, and winders at the top. These winders extend beyond the hall into the ceiling of the dining-room, (as sketched), but do not interfere

ment Station" to each farm where these experiments are tried, and supplies to the owner the information he wants, at small cost, if any—perhaps a profit. Neighboring farmers having very similar soils will also be benefited.

A Cottage, Costing \$800 to \$1,050.

BY R. B. REED, ARCHITECT, CORONA, LONG ISLAND, N. Y.

This design is an enlargement of the small cottage described on page 92 (last month), and the two plans and their descriptions should be read together, to best understand them. The arrangements are very complete in convenience, appearance, and economy....**Exterior,** (fig. 1).—The outlines and style are simple. The front is enlivened by the Porch, Bay-Window, and other projections. The details of finish are of neat design, and in harmony, giving an agreeable expression of taste and refinement—features especially pleasing in cottage architecture....**Cellar,** (fig. 2, placed for convenience on page 131).—Height in clear, 6½ feet. It is under the main building only; has two windows, and stairs leading to the first story. It contains 378 feet area, giving abundant room for all ordinary requirements....**First Story,** (fig. 3).—Height of ceiling, 9 feet. The best use is made of the space, by having but few divisions, leaving the rooms of good size. The Hall is small, but is conveniently arranged to answer all necessary purposes. It is entered from the front porch, and communicates directly with the parlor and dining-room, and by the main stairs with the second story. There is sufficient room for a hat-rack at the right of the front door. The Parlor is of fair size, and the large bay-window adds materially to its area and cheerfulness. With very little expense in furniture, this apartment may be made pleasant and cosy. The Dining-Living-Room extends the whole width of the house, with a window at each end. It is conveniently arranged, with doors opening from the

windows have semi-circular heads outside. In their construction the frames and sash are square, to admit ordinary curtain fixtures on the inside. The circular head is outside of, and "planted" on the flat casing, or "blind strip," and is made perfectly tight by a flange of tin. The additional expense of such circular finish is but trifling, compared with its good appearance. The side and rear windows have square heads, with rebated drips. Blinds are intended for all windows above the cellar. Ventilators are placed in each gable. The Porch has boxed pedestals, and columns, scroll-sawed ballusters, and circular spandrells. The inside walls and

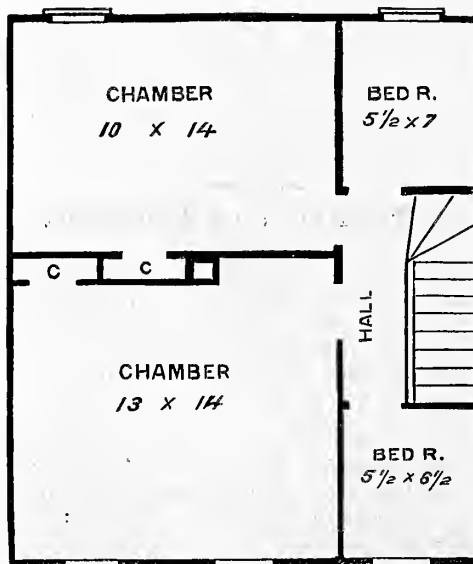

Fig. 4.—PLAN OF SECOND FLOOR.

ceilings are "sand-finished" on two coats of brown mortar. The main stairs are constructed with a

Fig. 3.—PLAN OF FIRST FLOOR.

with its use, or seriously injure its appearance. The Bay-Window is neatly arched on the inside. Marble mantels are put in the parlor and dining-room, and shelves in the chambers. The second story hall is lighted through the door (sash) of the front bed-room....**Suggestions.**—This plan was arranged to suit a village lot 25 feet in width, leaving a passage-way at the side. This necessitated placing the wing at the rear of the main house. If there is more ground, the wing may be placed at the right of the main part, facing the road. The communications between the dining-room and wing, would still be similar to those shown. The window at the right of the dining-room would be placed in the rear. These changes entail no extra expense, if determined on before commencing to build.

Estimate, cost of materials and labor for main house:

56 yards excavation, at 20 cents per yard.....	\$ 11.20
875 feet stone foundation, at 5 cents per foot.....	43.75
2000 brick, (furnished and laid), at \$12 per 1,000.....	24.00
340 yards plastering, (complete), at 25 cents per yard.....	85.00
1236 feet of timber, at \$15 per M.....	16.89
2 sills, 4x6 in. 24 feet long.....	27.50
2 sills, 4x6 in. 21 feet long.....	32.40
2 ties, 4x6 in. 24 feet long.....	18.00
4 ties, 4x6 in. 21 feet long.....	6.75
250 wall strips, at 11c. each.....	1.60
162 siding, (9 inch), at 20c. each.....	30.00
Cornice materials.....	28.00
135 shingling lath, at 5c. each.....	6.75
24 bunches shingles, at \$1.25 per bunch.....	30.00
112 flooring, (9 in.), at 25c.....	28.00
2 cellar windows, (complete), at \$4.....	8.00
1 bay window, (complete), at \$40.....	40.00
5 plan windows, (complete), at \$12.....	60.00
Stairs, (complete), \$10; 12 doors, (complete), \$90.....	136.00
Mantels, \$39.91; Porch, \$30; Closets, \$10.....	79.91
Nails, \$3; painting, \$50; Carving, \$12.....	71.00
Carpenter's labor, (not included above).....	80.00
Total cost of main house.....	\$300.00
Add last month's estimate for wing.....	250.00
Total for whole complete.....	\$1,050.00

The Duchess of Hillhurst 3rd.

Another notable Duchess has made her mark in the world; and it is one of American lineage and birth. This is Duchess of Hillhurst 3rd, a Shorthorn heifer owned by Mr. Loder, of England, but bred by Mr. Cochrane, of Hillhurst, Canada, and

—a rich red—the outline is a tracing of the original, and represents the form of the heifer with exactness. The sire of the heifer is Duke of Hillhurst 2nd, a descendant of the Hillhurst herd, owned by Mr. Cochrane of Canada. The branch of the Duchess family, to which this animal belongs, is much more vigorous and productive than the pure Duchesses, and is, in fact, the only offshoot of the family

horses, to be kept on hand even in times of peace, and in war the consumption is very great. Every few years, European journals are alarmed at the scarcity of horses, and just now the English people are anxiously asking where a supply could be procured for their cavalry, in case of war. In this event there would certainly be a demand for our animals, larger than we could supply, and in any

SHORTHORN HEIFER, DUCHESS OF HILLHURST 3RD.—Drawn and Engraved for the American Agriculturist.

purchased by her present owner at a recent sale of imported stock in England, for 4,100 guineas, or \$21,525—a remarkable price for so young an animal, scarcely more than a calf. It is possible that she, as an article of merchandise, is worth all she brought. Breeding animals are not to be justly valued by the price of beef or of milk, and if one of her progeny should turn out to be as valuable a breeder as one of her related race, the Duke of Airdrie, which has the deserved reputation of being the parent of more valuable animals than any other bull, and by far the best Shorthorn bull ever seen in America, the price may well be considered as moderate, even in these depressed times. This animal has been universally accepted as a model Shorthorn, and certainly no one can refuse to admit, at first sight, that she possesses, in perfection, all the beauties of this fine race. Her form and features are perfect, and are admirably represented in the colored print from which the engraving was made. This print is given in an extra sheet by the "London Agricultural Gazette," a journal which has done good service to the Shorthorn interest, in steadily opposing the delusive style of picturing animals, which has, unfortunately, become so popular, both in this country and in England. While our engraving can not give the color of the animal

which continues to increase in number. Unfortunately this Airdrie branch has been almost entirely lopped off from this side of the Atlantic, so that but one pure descendant of this important family, and that as yet unproductive, remains in America.

The Exportation of Horses.

Several hundred head of horses were sent to Europe last year, and recently a number were shipped through the agency of Mr. Stoddard, of 626 Greenwich St., New York. This, we believe, is the first shipment from New York, and is the beginning of an important business which must grow to large proportions in the course of time. We have a class of horses that are admirably fitted for cavalry purposes, and for road uses. For this we have to thank the breeders of trotting horses, who have, during many years of careful improvement and training, supplied the country with a most useful class of animals. The racing horses of Europe can not compete with our trotters, either for the road or for the purposes of war, and now that the value of our horses has been discovered, we look for a permanent market for them in Europe. The frequent European wars call for a large supply of

case it is probable that all of our surplus stock will find ready and profitable sale in foreign countries.

In view of these circumstances, it would be well for us to consider how we can improve our stock, so that farmers may be able to take a share of this business. It has been too frequently the case that farmers have not only begrudged the cost of the services of a good sire, but they have also reserved for breeding only the poorest of their mares, lest the better ones might be forced to lose a few weeks work in the spring. Spavined, wind-broken, worn-out mares, have been used for breeding, until a vast number of horses are constitutionally prone to disease, and are of little value from their birth. It costs no more to raise a good colt than a poor one, and if farmers would keep a good brood mare or two, and would secure good sires, a mare might be made as profitable in her increase as two good dairy cows, without considering the value of her work, which, at the least, will pay for her feed. It is an established fact, although it may seem at first sight to be an anomalous one, that the more we substitute railroads and steam-engines for horse-power, the greater demand we create for the services of horses. Horse-power is, after all, only a feeder for steam-power, and the more steam-power we use, the more horse-power we shall need to supply it.

Among the Farmers.—No. 27.

BY ONE OF THEM.

Corn and Cob Meal.

Well do I remember, as a youngster of nine to eleven, how I delighted to be perched upon Old Gray, between and upon sundry bags of corn and rye, or wheat, and started off for the mill. I could fish until the grist was ground, and no boy ever had, in his own view, a choicer lot of lines and hooks. The country mill of to-day is much like that of my boyhood; the miller is just as chatty, and just as dusty, and the farmers just as stupidly bring their corn on the ear. I had supposed that the custom was dying out; but no—hundreds of thousands of bushels are ground every year, and are likely to be. I asked the miller, "How is it that you grind corn on the ear? Do the farmers really think the cob is worth anything as feed?"—"No," said he, "they know it is not. I grind thousands of bushels, because they bring it here, but they never *buy* any, if there is any other feed they can buy."—"What is their notion?"—"They know that there is not as much good in a hundred bushels of cobs as in a pint of meal, and they have the cobs ground from sheer laziness."—That reason never occurred to me before. We use no power shellers in this part of the country, and it is no small job to shell by hand. The fact that the cattle and horses eat the cob meal, is patent; that it *does* them no good, is not so clear. Indolence catches at the idea that they would not eat it were there not some good in it, and so, as it is much easier, and as it has been customary to grind cob and corn together, the mills are made to do it, and the millers really forced, against their own good sense, and against their will, to grind them. I have no doubt it is true that corn and cob-meal fed pure—that is, simply "wet up,"—is less likely to do harm than pure Indian meal; but fed as it ought to be, it is certainly less likely to do good—which is more important. I think Indian meal never ought to be fed to cows, or any ruminants, unless in the form of a thin gruel, which farmers call "slops," or upon cut hay, straw, or chaff. Now rye straw is somewhat nutritious, and really of some benefit to the beasts, whereas the digestion of corn-cobs, which the animals are forced to go through with, is a tax upon their systems that results only in harm, except in so far as the mechanical distension of the stomach offers a similar advantage to that secured by feeding meal upon straw or hay. I saw at the mill a very

Light and Handy Bag-Holder.

It was made of a crooked branch, **U** shaped, into which three or four sharp hooks were driven on the inner side, to hold the top of the bag; the whole being supported upon three straight light legs. Almost any old orchard will furnish branches out of which similar pieces of wood might be cut and shaped. Such things are very handy, now and then, and upon large farms it is well enough to have a plenty of them, but on such a farm as mine they are in the way. I have "tinkered up" many a handy contrivance, which never was used half a dozen times, and which, for years, was either under foot, or taking up valuable space somewhere, until it was made into kindling-wood. Two little hooks, set in one side of the fanning mill, to hang the edge of the bag on, is the most convenient bag-holder for people who need one so little as we do.

Stealing Poultry—Marking.

Nothing is more exasperating than the loss by theft of one's choice poultry. We are not particularly liable to have pigs and sheep stolen, and it is still more rare to hear of a young "beef critter" being found missing from some mountain pasture. I can sympathize with those farmers of the South, who have not only poultry, but pigs, no matter how choice, made off with, and do not blame them for making no more efforts to introduce choice stock, especially when the well-bred stock are more easily caught than others. This is certainly true of some kinds of poultry. All the Asiatics, Dorkings, Plymouth Rocks, and the French fowls, are more easily caught than other breeds. Hamburgs, Leg-

horns, Games, and some other kinds, are seary and noisy—thus they alarm the dog and the owner.

A friend of mine, on Long Island, has had his choicest Brahmas twice selected out carefully by thieves, breaking up his breeding pens, and putting him, of course, to heavy loss and much perplexity. It is very difficult to trace such a theft, for only the owner knows his own birds, and they can not be described so that another person can readily recognize them—unless, indeed, by some cutting of the web of the toes, they may be marked. I suggested to him dyeing the fowls of each breeding pen. Some of the brilliant aniline colors, pinks, and purples, might be used, and no one would dare to take such fowls. They would not only be marked birds, but each single feather would be a tell-tale, whether dropped along the highway, or found anywhere else, on or off the fowl. So obvious would be the danger, that no thief would be bold enough to take the risk. These dyes are perfectly innocent, easily applied, and can not be removed until the fowls moult.

Blood and Breeding.

Changes in form in domestic animals are brought about with more or less rapidity through circumstances under the control of the breeder. Structure, established by generations of careful breeding, with certain objects in view, is characteristic of any fixed breed or type of animals. The moment the surroundings change, and the system of breeding, (that is, selection of breeding animals), which has formed or maintained certain structural peculiarities, is given up, the progeny change back (revert) or take on changes adapted to their new conditions of life. An interesting, though by no means unusual or surprising fact, has lately been brought to my notice, showing how rapidly this return to the feral, or wild condition, changes structure. A gentleman of this vicinity sent to Virginia a pair of carefully bred Berkshires, with remarkably short faces, and otherwise of approved shapes—broad and level, with well developed hams and shoulders; low set, with small offal, fine-haired, etc. The progeny of this excellent pair have since been bred together, a portion of them being kept confined, the others allowed to run at large in the woods, and take their chances with the "Razor-backs" to the "manner born." The result is, that those bred in confinement, and, so to speak, *luxury*, have still short faces, and other characteristics of well-bred Berkshires; while the others of the later generations, though just as pure as to blood, have changed greatly; fallen off in size somewhat, have straighter and longer snouts, are getting slab-sided, and gradually approximating the half-wild type.

Another fact seems to be proved, which rather surprised me, and yet should not. It is, that even these partly reverted Berkshires do not hold their own in the woods with the natives. That they are not so prolific, and do not make so much pork, and even the pork is not superior, unless the pigs are taken up and fed a little while before killing.

The delicacy of Virginia mast-fed hams is well known; their excellence arises from two or three distinct causes. One of these is the health of the pigs; another is the fact that, during much of the year, it is, "root, hog, or die!" and then, when the woods are full of chestnuts, chinquapins, acorns, and other mast, they pick up a living very easily, and fatten up a little—enough to make their flesh juicy and tender before killing time; and another cause, undoubtedly, is that this food is sweet, wholesome, and both it and they far removed from their ordure. If it be really true that for this wild life, the native hog is the most economical producer of pork, and that the pork is of the best quality, it is time that we knew it, and it would pay somebody to undertake the demonstration.

Pigs in the California Drouth.

An old friend, for some years a resident of Santa Barbara Co., Cal., writes me, that before the close of the terrible drouth, which for more than a year afflicted that region, most of his pigs had succumbed, the few which survived were valued, of course, for the particular quality of being able to live on "faith and a promise," without much, if any, more substantial provender. My friend wishes

to know which breed of swine will thrive best on this diet. What kind of pigs live on the least food, and on coarse food. I believe that, as a rule, the wild, or half-wild pigs can bear hunger best, yet when they get a chance, they eat voraciously, but do not fatten. The most improved breeds, the small Yorkshires, for instance, live on the least amount of food, and if they get a surplus—that is, more than enough to sustain life—they lay it up against a hungry day, in the form of fat, so that, other things being equal, it seems clear that such pigs will prove the most economical where long drouths are to be guarded against. The small Yorkshires, and the best strains of Essex pigs, are *always* fat with the commonest feeding and care; hence, always prepared for a drouth. I do not believe the "Landpikes" would stand starvation commons half so long, and am sure that the half-bred, or half improved cross-bred breeds, like Chester-Whites, Durocs, Poland-Chinas, would not, for they require more food, and are neither accustomed to occasional protracted abstinence, nor will they keep fat upon ordinary non-fattening food.

Irish Butter.

Our village doctor was for many years a surgeon in the navy, and he tells me that all navy men, and officers of the merchant service also, who have occasion to lay in stores for use in hot latitudes, select Irish butter, and that this, bought with only the ordinary judgment of the mess eater, will keep sweet and flavorful around the world. The best butter they can buy in the Philadelphia market, will keep but a little while at sea, while the dollar-a-pound butter of the famous Jersey dairies, will hardly keep sweet ten days in warm weather. We have enough Irish dairymaids in this country to test the matter pretty thoroughly, and find out if it is in the making, in the grass, or in the kine. The cream of different breeds of cows makes butter, which varies in keeping quality, as much as it does in color—and I am by no means sure that the paler kinds of butter do not uniformly prove of the best keeping qualities. There is, in my mind, a great distinction between pale butter and butter which has lost its color. The cream of a pure Jersey, or even Guernsey, herd, may be "whipped to death" in the churning, and the butter "come" colorless and sickly-looking—whereas the same cream, properly churned, might produce beautiful yellow butter. The pale tint is certainly not the natural color of the butter. The best keeping butter in the New York market, has more or less color, according to the time of the year, but it has a fair color, and is never, perhaps, very pale. I would not say that the paler butter is, the longer it is likely to keep, but I think that the highest colored butter, whether the color be natural or artificial, is not nearly so likely to keep as well as the paler kinds. No doubt salt has much to do with the keeping of butter, and our dairy people can not be too careful in this respect. It is perhaps a question whether the purest salt is the best. Certainly an ounce of saltpeter to the pound of salt, ground together, and used just as pure salt would be, not only has no bad effect, but undoubtedly imparts a keeping quality superior to pure salt, [which we do not admit.—Ed.] Sugar is a well known and powerful antiseptic, and has been used for keeping butter with good effect, the quantity being not sufficient to impart perceptible flavor, say one or two ounces to the pound of salt. I find that packers of summer butter, which is intended for winter use, put about one ounce of salt to the pound of butter. We never salt so heavily in making for our own use, as we do not enjoy butter made with more than half the above named quantity. Last summer we employed

An Irish Dairymaid,

at least a young woman newly-arrived, who had been bred to the work of the cow-byre and dairy. She made excellent butter, following the usual course, except that she worked the butter *only once*, first working out the buttermilk, washing a little, and then working in what she called *dissolved salt*—that is, fine salt mingled with water, which of course dissolved a good part of it. This salt and brine was, to a great extent, taken up by the butter, and the water, subsequently, but during the

same operation, worked out. We usually work out the buttermilk, salt, and after eight to twelve hours, work again, and thoroughly. Her butter was excellent, and kept well—rather better, perhaps, than if it had been worked twice in the usual way; for there is such danger of breaking the butter globules, that it is better to err on the side of hardly working enough, than to work it too much. It takes considerable hard work to make the butter appear greasy, from the broken butter globules; yet, doubtless, a few globules break very easily in the operation. We all know that greasy butter will not stay sweet; hence, the problem is, to remove the buttermilk, with the least possible working.

It is only a few days ago, that a gentleman who used to live at Antigua, in the West Indies, was at my desk, on some business, and stated that the best butter ever received in those hot ports was Irish butter; that it was never, in his experience, other than sweet, and excellent, and that after a firkin was opened, it kept until it was consumed.

Talks on Farm Crops.—No. 14.

By the Author of "Walks and Talks on the Farm,"
"Harris on the Pig," etc.

I anticipate great things from Prof. Atwater's Farm Experiments. That was a grand idea, putting up small packages of different manures of known composition, and letting farmers try them on different soils and on different crops. I hope the good work will be continued, with such changes as experience shall show to be necessary. And I hope in all cases one or two plots will be left without manure of any kind. [Of course the writer did not know of our plan for Experiment Stations all over the country, given last month on p. 86.—ED.]

Indian corn has long been, to me, one of the mysteries of our agriculture. It is a grand crop. In chemical composition, Indian corn and wheat closely resemble each other. And yet, on a great variety of soils, without manure, one acre of Indian corn will yield double the amount of produce as an adjoining acre sown with wheat. In other words, it is as easy to grow 30 bushels of shelled corn per acre, as 15 bushels of wheat per acre.

I think the rule would hold good on a great many farms in this section. It is due probably in some degree to the fact that Indian corn grows later in the season, and during very hot weather. It takes up from the soil, and evaporates through its leaves, an immense amount of water, and consequently is able to take up a much larger quantity of nitrogen from the soil. If land, in good condition for wheat, with season favorable, produces 15 bushels of wheat per acre, I think the reason it does not produce 20 or 25 or 30 bushels, is due to a lack of available nitrogen in the soil, and possibly to a deficiency of available phosphoric acid. There is enough of it in the soil, but the wheat is not able to take it up—while the corn is.

"A bushel of corn and stalks," said the Doctor, "contains about 4-lb. of phosphoric acid, and a bushel of wheat and straw about the same amount. And we shall not be far wrong in assuming that a bushel of wheat and straw contains 1½ lb. of nitrogen, and a bushel of corn and stover about the same. Why a given piece of land that will only grow, without manure, 15 bushels of wheat, will grow 30 bushels of corn, is a question that, at present, can not be answered. You need more experiments, and Prof. Atwater is entitled to great credit for what he is doing in this direction."

"All of which," said the Deacon, ironically, "is wonderfully interesting. Assume, for the time being, that the reason is because the corn, growing in warmer weather, and perspiring freely, can drink a much larger quantity of water. If it sucks up twice the water from the soil, it would get twice the amount of phosphoric acid, nitrogen, and potash. This is easy enough to understand, and you may as well take it for granted and go on with your story."

"Very well," said I, "then it follows that (1) if corn and wheat brought the same price, corn would be a much more profitable crop for the 'chemical

farmer,' than wheat. The wheat might leave more than half the 'chemicals' in the ground, while corn might take up two-thirds or more of them. (2). It follows, too, that land may be much more rapidly and completely impoverished by growing corn, than by growing wheat, but (3), on the other hand, if the crop is fed out on the farm, corn can be used to great advantage in developing and increasing the fertility of the farm. It will gather up the nitrogen, phosphoric acid, potash, etc., from very weak solutions in the land, and when the crop is fed to animals, from 80 to 95 per cent of the valuable ingredients of plant-food will be left in the manure, and the manure can be used for growing crops which need a larger supply of plant-food in the soil, and which command a higher price."

"That is not a bad idea," said the Doctor. "You can grow corn, and, by feeding it out on the farm, make your land rich enough to grow good crops of wheat, potatoes, barley, etc. All these crops, in proportion to the nitrogen, phosphoric acid, and potash that they contain, usually bring a higher price than corn."—"In some parts of the West," said the Deacon, "one bushel of wheat will buy four bushels of corn, and even here one bushel of wheat will buy 2½ bushels of corn."

"And yet," said I, "a bushel of wheat takes no more plant-food out of the soil than a bushel of corn. Corn and clover can be grown cheaply on good land, simply because they can live and thrive on soil that does not contain sufficient available plant-food for profitable crops of wheat, barley, etc."

"The experiments published in the *American Agriculturist* for February," said the Doctor, "possess unusual interest. On Mr. Birdsey's farm, three of the plots dressed with nitrogen and phosphoric acid, produced 20 bushels of shelled corn per acre. On two other plots, where potash was used alone, and with nitrogen and phosphoric acid, the yield in both cases was 48 bushels per acre. It seems clear that the soil was deficient in potash. It contained enough available nitrogen and phosphoric acid to produce 48 bushels of shelled corn per acre, and it produced only 20 bushels simply from lack of potash. When this was supplied, the yield rose up to 48 bushels per acre."

"But this is not by any means a maximum crop," said the Deacon, "and it is curious that some of the plots dressed with nitrogen, phosphoric acid, and potash, did not give a larger yield."

"The reason," said I, "seems to be this. The soil was really deficient in available potash. It takes nearly 2 lbs. of potash to produce one bushel of corn and stalks, cobs, etc. On Plot No. 5, 53½ lbs. of potash, 17 lbs. phosphoric acid, and 10½ lbs. of nitrogen, were sown per acre. This dressing increased the crop 28 bushels per acre. It would probably have been more if more potash had been applied. The nitrogen and phosphoric acid could do no good, because there was not enough potash to produce a larger crop. On Plot 3, 160 lbs. of potash alone was applied per acre, and the yield was no larger than where 53½ lbs. were sown. There was nitrogen and phosphoric acid enough for only 48 bushels per acre, and the excess of potash could not raise it above this point."

"This experiment," said the Doctor, "shows that while there are occasionally soils which, owing to peculiar treatment, such as the use of bone-dust, fish manure, dried blood, etc., are relatively poor in potash, and rich in nitrogen and phosphoric acid, yet, even in this case, a large and profitable crop of corn can not be grown by the use of potash alone. We need nitrogen and phosphoric acid, in addition to the potash, to produce a maximum crop. The climate or season was probably capable of producing 70, 75, or 80 bushels of corn per acre, and the reason why Plot No. 3 produced only 48 bushels was, probably, due to a lack of nitrogen and phosphoric acid."

"In Mr. Bartholomew's experiments," continued the Doctor, "phosphoric acid seems to have been the weak link in the chain. The 'No Manure' Plot produced about 16 bushels of corn per acre; plaster alone increased the yield to over 19 bushels per acre. Plaster and 17 lbs. phosphoric acid, increased the crop to over 33 bushels per acre; plaster and 25½ lbs. of phosphoric acid increased the yield to nearly 38 bushels per acre; while plaster

and 51 lbs. of phosphoric acid increased the yield to over 41 bushels per acre. The reason none of the plots did not yield over 41 bushels per acre, is probably due to a deficiency of nitrogen in the soil. In this case, therefore, as in the other, the evidence all tends to show that if we want a good, profitable crop of corn, we must in some way furnish a liberal supply of nitrogen and phosphoric acid. Hen manure and plaster gave a yield of 56½ bushels shelled corn per acre."—"Good," said the Deacon, "I always told you that hen-dung and plaster would beat your artificial manures."

"It is a capital manure," said I, "but you can raise just as large crops of corn with artificials as with hen manure. What we want is a good supply of nitrogen and phosphoric acid."

And now, how are we going to get nitrogen and phosphoric acid? It seems clear to my mind that we can not afford to pay 20 cents a lb. for nitrogen to raise corn at 25 to 50 cents a bushel. Where we can get 75 cents a bushel, and can make good use of the "stover," it may pay well to use artificial manures for corn, but even in this case I am inclined to think it will be better to use the artificial manures on some other crop, and plant corn afterwards to gather up the nitrogen, phosphoric acid, and potash that they leave in the soil.

We can not be too often reminded that it costs just as much to plow, harrow, roll, mark-out, plant, cultivate, hoe, and cut up an acre of corn that produces only 16 bushels, as one that produces 70 bushels. What we want to ascertain is, how to produce good crops. It is all very well to tell us that a few pounds of phosphoric acid will increase the yield of corn from 16 to 41 bushels per acre, and that at 70 cents a bushel the application of this manure affords a profit of \$12 per acre. This is true. But we might better say "if we use the superphosphate, the loss of growing corn on such land will not be as much by \$12 per acre as if we planted the field without manure."

We must first ascertain how many bushels per acre it requires to pay expenses, interest on land, etc., and then, if we know how much it costs to increase the yield over and above that amount, we can tell whether we are making or losing.

As far as possible, we should aim to raise corn on land naturally rich enough to produce a fair crop without manure. If we have a piece of low, rough land, that needs nothing but draining and cultivation to make it rich, there is the place for corn. Drain this land and get a big crop of corn from it, and use the corn and stover to feed out and make manure for the poorer, upland portions of the farm.

On good, clean, highly cultivated land, where we can use the reaper and mower, it is not clear to my mind that corn can be grown to advantage except as a "fallow crop." If we want to clean the land, or if it contains a quantity of plant-food that wheat or barley, or potatoes, or hay, can not utilize, we may plant corn with great profit. But we should rarely plant corn on land that is capable of producing good wheat, barley, potatoes, roots, and hay, and where these crops can be sown and harvested to advantage, unless it is for the purpose of cleaning the land, or for utilizing the plant-food which the higher priced crops leave in the soil. I feel certain, at any rate, that it will be rarely good management to raise corn on such land, and sell it at ordinary prices. We can afford to raise clover on our farms, but it is seldom, indeed, that we can afford to sell it. We had better sell timothy hay. It takes less from the soil, and brings a higher price. So it is with wheat, and barley, and potatoes. Corn and clover are grand crops, but unless you have new, rich, cheap land, you can not afford, at ordinary prices, to raise them to sell.

GAIN OF WEIGHT IN GOOD STOCK.—It is one of the advantages of keeping good stock, that not only is more flesh gained for the quantity of food consumed, and a better quality of flesh produced, but the waste in the shape of offal is greatly reduced. The Shorthorn heifer "Miriam," bred by Mr. J. Stratton, which was awarded first-prize for the best female at the Butcher's show at Islington, England, last year, weighed alive 1,868 lbs. The

dressed weight was 1,346 lbs., giving over 72 lbs. dressed to the 100 lbs. live weight. Perhaps there is no other animal than a very good Shorthorn, that would dress so well, and an instance so well authenticated as this, shows the value not only of the breed, but of good feeding as well.

A Cheap Poultry House.

Mr. "W. A. B.," Caroline Co., Md., sends the following description of his poultry house, suitable for those who need a cheap building, and can do the greater part of the work themselves. The plan is given in figure 1. The center building is 10 x 10 feet, and is 6 ft. to the eaves. The wings are each

Fig. 1.—GROUND PLAN OF POULTRY HOUSE.

8 x 6 x 4 feet. Either of the three parts may be built first, and the others may be added from time to time. No posts are used in building it. The sills, 3 x 4 in., and 10 ft. long, are mortised and put together in place; the plates, 3 x 3 in., and 10 feet long, are put on the sills; then eight boards are cut six feet long, four of them with the angle at the top to correspond with the pitch of the roof. These are nailed to the sills, and those in front and back nailed to the edges of those on the ends. Then four sticks are cut each five feet six inches long,

coops on each side, in each wing, twenty in all, (18 x 18 x 20 inches). These are closed inside with slats, and each one is independent, and entered from the outside, as shown in figures 2 and 4. The entrances to the nests are in the doors, as in figure 2. Figure 4 is an inside view of one of the wings, showing the interior arrangement of one side. The two windows in front, one in each wing, three doors, and twenty-three entrances for the fowls, will give sufficient ventilation, but if more is needed, small doors or windows, 18x18 in., can be put above the plates, in the ends of the center building. The cupola is not necessary, but it allows the foul air to escape; it costs about a day's work for a handy man, and is built of scraps. The cost is for 875 ft. of lumber, \$14; shingles, laths, and strips, \$16.75; nails, hinges, glass, screws, and putty, \$3.75. Total, \$34.50, for materials. The roof need not, of necessity, be shingled, but it will be found the cheapest in the end, and at the same time it looks better.

Fig. 4.—SECTION.

Goat Keeping for Profit.

The number of goats kept in the United States is rapidly increasing. Large flocks exist in parts of California and Texas, and many persons are turning their attention to the keeping of these animals as a profitable occupation. In some localities, goats are kept for their milk, and for this purpose they may be doubtless made still more widely useful. But goats can not be kept in large flocks for milking, nor is the flesh at present marketable. The profit from the goat can come only from the skin and the hair. A large quantity of goat skins is yearly imported for tanning, to produce morocco leather, and

the hair of the common goat is valued for the plasterer's use. The Angora goat bears a fleece of "mohair" that is valuable for several different manufactures, and the Cashmere goat has an undergrowth of fine wool, from which the most costly shawls are made. By crossing with the Angora males, the common goat can soon be bred up to a point where the fleece is worth as much as that of the pure bred, and it is evident that if the largest profit is desired, the best animals should be kept. The goat will thrive where the poorest sheep would starve, and it better enjoys the rough fare of rough places than the sweetest pastures of grass.

There are many rocky and half-barren localities that might be put to good use by being turned into goat pastures, and there are many better pastures, ill-fitted for the less hardy sheep, upon which goats could be successfully kept. While much harder than sheep, and less subject to destruction by dogs and wolves, goats have yet some diseases of their own to contend with. Of these, foot-rot is the worst, and diarrhoea and dysentery are sometimes troublesome. Of parasites, the house is the only one that is seriously injurious, and this is not at all difficult to deal with. Foot-rot, and the other ailments of this animal, are to be prevented, or treated, precisely as those of the sheep; and precautions to

avoid damp and close confinement during the kidding season, are necessary. In general, the management of a flock of goats differs in no material respect from that of a flock of sheep, the rules for feeding, breeding, etc., of the one, apply equally to the other.

Scoops for Sowing.

In sowing fertilizers or plaster, it is disagreeable to use the hands. A convenient implement for this purpose may be made of a piece of tin plate (a fruit can, which has served its first use, will furnish the material), cut in the shape shown at figure 1. This is then bent around a circular piece of board, and nailed with a few tacks or shingle nails. A handle is then inserted as shown at figure 2, and the scoop is complete. Various sizes may be made, one that will hold a quarter of a pound, will sow as near as need be, 100 lbs. per acre, each cast covering a space 16 feet long by 8 broad; 350 of these casts will cover an acre, and will use nearly 90 pounds of material. If double this quantity is to be sown, and great evenness is desired, it would be best to use the quarter-pound scoop and sow both ways. The same sized scoop would sow 6 pecks of wheat per acre. In using these scoops, it is necessary to give them a sudden slight twist, just as the contents are thrown out; this spreads the material in a broad sheet which covers the space mentioned, or may be made to do so by a little practice. Great skill in using these may be gained by practising with a pailful of sand, dry ashes, or lime, upon plowed ground. The sown material is then easily seen.

Fig. 1.—TIN.

Fig. 2.—SCOOP.

A Road Leveler.

We recently saw a machine in use to level some ground that had been graded down, which operated very effectively, and would serve a good purpose in smoothing roads. As this work will soon be necessary, we give an engraving and description of this implement. It consists of a frame of 8x6 inch hard-wood timber, made as shown in the engraving, with the ends rounded, so that it will slide over the ground easily. Near the center, the scraper is pivoted on two one-inch iron bolts. The scraper is made of a plank, a foot or more in width, with a slightly curved steel edge, bolted in the front. It is connected with the frame by two side-pieces of hard-wood plank, strongly bolted to it, as seen in the illustration. A pair of plow-handles

SCRAPER FOR LEVELING ROADS.

is fixed to the back of the scraper. The machine is drawn by an ordinary elevis, fixed to the front bar, and a short chain. It should be about 10 feet long, and 6 feet wide, to be used with a pair of stout horses or a yoke of oxen.

A Cheap Drain.

Where neither tiles nor stones can be easily procured, a good, useful drain may be made of hemlock lumber. In soil always wet, such as swampy meadows, or where springs abound, hemlock will last many years. The drain, of which the engraving

Fig. 2.—FRONT ELEVATION OF POULTRY HOUSE.

the plate is raised up, a stick put under it on the sill, in each corner; the boards are then nailed to it, and the frame is raised, boarded, and battened, and it is strong enough. The roosts are arranged as in figure 1; the piece, C, rests on the plates, and is held in place by cleats, and acts as a hinge. The pieces, D, are secured to it, and the roosts, B, to them.

At A is a ring bolt, and over head a hook. When the house is to be cleaned out, the roosts are raised and hooked up, and are six feet high, so there is no trouble working under them. The door, E, is 6x3 ft. In each wing there are two rows of nests,

Fig. 3.—END ELEVATION.

each nest 18 x 18 x 12 inches, 12 in a row, 24 in each wing, and 48 in all; the bottom of the lower row is two feet from the ground, and under it are five

ing shows a section, is made of pieces of 2x4 scantling, and boards 7 inches wide. This gives a water space of 4x5 if the scantlings are set upon edge, and 2x4 if they are laid flat and the boards overlap an inch and a half. The water-way may be made larger by hollowing a channel in the bottom. When stones can be procured, this drain is still to be recommended, because the stones can be placed above the boards, as shown in the illustration, and a permanent bottom is thus provided for the stones. When a large volume of water is escaping, both the upper and lower drains will be in action, and otherwise only the lower one. Should one of the drains be stopped, an outlet will be found through the other.

SECTION OF DRAIN.

Aids in Fence Building.

One man, alone, finds it a difficult job to build a board fence, inasmuch as one pair of hands can not readily hold both ends of a twelve-foot board, and nail one end at the same time. By using the hooks shown in the accompanying engraving, this work may be easily done by one person. In the figure is shown a hook and guard for holding the end of the board that comes next to the finished panel. It is so made that, when hung upon the top of the fence post, the board rests upon the hook, and can not slip off. Then the other end of the board is nailed, the middle is nailed, and then the end held upon the hook. The hook is then moved for the next place. To hang the rest of the boards, hooks, such as shown at the left, may be used, of various lengths to suit the different spaces between the boards. The uses of these are too obvious to need description.

FENCE HOOKS.

Covered Cattle Yards.

As the feeding of cattle must necessarily become an important part of our system of agriculture, the study of the best methods of sheltering and feeding animals becomes of interest. This subject has long occupied the attention of English farmers who have been obliged, for the sake of economy of manure, and for the comfort and thrift of the stock, to furnish most complete covered yards in

Fig. 1.—CROSS-SECTION OF COVERED CATTLE YARD.

which to feed the animals. A substantial and complete yard for this use has been recently erected, enclosing a space of 112 feet long by 80 feet wide—large enough to accommodate 75 head. The roof rests upon outside walls, and two rows of iron pillars, 10 feet long, support it on the inside. The pillars are 5 inches in diameter, and rest upon foundations of stone work. The center roof rests upon plates, which are supported by the pillars; the outside roofs rest upon flanges upon the posts; the latter are lower than the former, the difference leaving a space for ventilation, and also an escape for the rain water, which is caught in 6-inch gutters and carried off. The roof timbers are all 9 inches by 3, and are tied by iron rods, as shown in figure 1. The portions of the central roof are laid flush,

and held in place by blocks and braces; this is to raise the roof so much more, and to provide a large space for ventilation. The rafters are 18 feet long and 3 x 2½ inches thick. Portions of the roof are glazed to admit a plenty of light. The total cost of the whole building was less than \$1,500. The space enclosed is nearly one thousand square yards, or nearly a quarter of an acre; the cost of the whole building is less than a dollar and a half for each square yard enclosed. The interest on the total cost at 10 per cent, which would repay the whole with interest at 7 per cent in less than 20 years, is \$150, or an annual charge of only two dollars per head of the stock accommodated. This cost is more than repaid by the increased value of the manure made, which has been found to be equal to 50 per cent; and by the saving of feed consequent upon the greater comfort of the animals, and this has been found to be equal to one-eighth of the usual amount consumed. So that in practice, instead of resulting in a charge upon the cattle, the use of these yards gives a direct and handsome profit upon the investment. At figure 1 a cross section of the structure is given, and at figure 2 a portion of the longitudinal section. The amount of

Fig. 2.—LENGTHWISE SECTION OF CATTLE YARD.

manure made by each animal fed in a covered yard, and littered with 20 pounds of straw daily, during the season of 6 months, may be estimated at 432 cubic feet, or nearly 3½ cords. Having had some experience in making manure in covered sheds, and knowing the extra value of such manure, we consider that if this were the only advantage gained, it would be sufficient to repay the cost of the yard.

AGRICULTURE IN KANSAS.—The report of the Secretary of the Kansas State Board of Agriculture, Alfred Gray, Esq., gives a very flattering account of the prospect for the coming year in that State. The condition of the winter grain is fully one quarter (25 per cent) above the average; and that of live stock is almost as favorable. Over a million acres of wheat was grown last year, yielding over 13,000,000 bushels. More rye was grown than in any other State in the Union; of corn over

two and a quarter million acres were planted, yielding over 40 bushels per acre, a total of over 103 millions of bushels; of oats 310,000 acres were sown, producing nearly 13 millions of bushels, or an average of over 40 bushels per acre.

AN UNTOWARD DECISION OF THE SUPREME COURT WITH REGARD TO TEXAN CATTLE.—Several of the Western States have a law prohibiting the passage of Texan cattle within their boundaries during the portion of the year when there are no frosts. This law is an absolute necessity to prevent the spread of the so-called Texan or Spanish fever, and the almost total destruction of native stock. A decision has been recently rendered by the U. S.

Supreme Court, which affirms that this protective law is void as being at variance with the Constitution of the United States. The States have the right to exclude any diseased stock, but it must be shown that the stock are really diseased. There is then no longer any protection for cattle, and unless Congress shall pass a general law, regulating the traffic in Texan cattle, disastrous losses will undoubtedly occur. Here is a case in which the Agricultural Department might take the initiative, and do a service which would be vastly more useful than fussing over the culture of tea and coffee.

How He Made a Liquid Manure Cistern.

“W. E.,” Jerseyville, Ill., sends a plan for constructing a liquid manure cistern in the barn yard, for receiving the drainage from the stables and the yards. It is not intended for the rain water from the roofs, although if this were permitted to flow into it, and the manure pumped out and spread upon grass land occasionally, it would be advisable. The cistern is 9 feet square, and lined with brick. A brick wall, enclosing a space 3 ft. square, is built in the center, and several openings are made in this wall, which is for the purpose of supporting the

PLAN OF MANURE CISTERN.

covering. The cover is of flag stones, 3 feet square, and there are 9 of these laid, as shown in the illustration. The cistern may be made as deep as may be desirable. It has 8 square feet of surface, and for each foot in depth will contain 20 barrels. If 7½ feet deep, it will hold 150 barrels, which will give a very good manuring to one acre of ground at the rate of nearly one barrel of the liquid fertilizer to the square rod. A square hole may be cut in the center stone to receive a pump.

A New Mangel—“Webb's New Kinver.”

In England, where root crops are of the greatest

“WEBB'S NEW KINVER” MANGEL.

importance, special shows are held of Mangels and Rutabagas. It is said that the Mangel known as

"Webb's New Kinver," has taken more prizes at the recent shows than any other. Mr. Wm. Crozier, of Northport, L. I., has cultivated it, and says, "it is the best Mangel I have ever seen." It is claimed for it, that it grows very smooth and uniform, has but a single tap-root, is very solid, and of a pale orange color. It is claimed that, in England, as much as 80 tons to the acre have been raised of this variety. The engraving shows that it is quite unlike the usual Mangels in shape. It is offered by Messrs. R. H. Allen & Co., of New York, as "the best Mangel in cultivation."

A Scoop for Measuring Feed.

Guess work is rarely economical. It is surprising how far from the truth many of our guesses will be found, if put to the test of accurate measurement or weight. In feeding it is best to be accurate. There is then no waste, the feeding is regular, and the cost is known with exactness. We are now using home-made scoops of the kind shown in the engraving, and find them convenient for feeding meal. The largest one holds two quarts, dry measure, and is 9 inches long, and $4\frac{1}{2}$ inches in diameter; thus holding, making due allowance for the slope at the mouth, about 135 cubic inches. It is cut from a sheet of tin 9×13 , which can be easily procured, and the edges do not meet exactly, thus making it $4\frac{1}{2}$ inches in diameter. The end is made of a piece of board sawn into a circle, or turned in a lathe, and an ordinary door-stop is used for a handle. A one-quart measure would be half the length of this, and if four quarts are needed, it is easy to take two of the 2-quart scoopsful. We find that one size is sufficient for all purposes, and to save the trouble of hunting them when they are wanted, one is kept in each feed-box and grain-bin.

SCOOP.

Fodder Crops—Which to Select.

Fodder crops, to be fed in a fresh condition to stock, are now recognized by thorough farmers as a necessity. Every year this system is practised more widely than before. As land becomes more valuable, and competition amongst farmers more close, it is found more desirable to increase the income from our live stock by all possible means. To enlarge our food supply is the most available resource. Pasturing is now only profitable upon cheap land, or such as can not be made arable. It is also found that to economize the physical exertions, and the consequent muscular waste of the animals, is a matter worth considering. The feeding of green fodder crops in yards, small fields, or even in the stalls, is, to a great extent, taking the place of pasturage of cows, horses, sheep, and pigs. We are obliged to make many blades grow where one grew before, to support the necessarily increased number of animals, and it has been found that by procuring a thrifty growth of green-fodder, we can feed as many animals from one acre, as we could feed from five acres or more of pasture. For cows and horses, it is necessary that these crops be cut and carried to them, else many times as much food would go under foot as would be eaten. But sheep and pigs may be made to consume the crops from the ground, by penning them within a narrow strip enclosed by hurdles or portable fences, that can be moved as the ground is cleared by them. The manner of feeding may be varied to suit circumstances, and every farmer can easily judge for himself what would be most convenient and proper for him. There is so much latitude in the choice and management of the different crops, that to select the best is sometimes difficult. There are early and late ones, and it is very important to alternate these so that the ground may be always occupied, and two or three may be grown in succession in one season. At present, fodder corn is grown more than anything else for this purpose, but there are several other crops, of quicker growth

early in the season, and that give an equally heavy product. Oats and peas mixed, $2\frac{1}{2}$ bushels of the former, and $1\frac{1}{2}$ of the latter, may be sown a month or six weeks before it is safe to plant corn, and will yield 8 or 10 tons per acre, of the best and richest milk-producing feed. Barley and vetches, mixed, and sown in the same proportion, are also a valuable green crop, and are especially well adapted to horses. Either of these crops may be followed by sweet corn of an early variety, and this may be cut and removed in time for a crop of millet or turnips. These three crops may easily be taken from the same ground in six months, and in the aggregate will yield 30 to 50 tons per acre without very copious manuring. Probably there are no others that are so prolific as these. It is widely supposed that there is no advantage in feeding sweet corn over the common field variety. The error of this is evident when we consider how much more sugar there is in the sweet corn than in the other, and sugar is nutriment. In many places near towns and cities, where green sweet corn ears can be sold, this crop may yield two profits, one from the ears, and the other from the stalks; some wide-awake farmers have discovered this, and take advantage of it. It is besides an excellent cleaning crop. Some experiments are being made in the Northern States in growing the southern "field," or "cow" pea as a fodder crop. How this will result we can not say at present; we have procured seed for a trial of this crop the present season. A bushel of seed per acre, should be sown in drills, and three months' time is required to mature the crop for cutting. In the South, this crop is of great value for feeding green, and with this, winter oats, corn, and millet, may be made to give a succession. Cabbages and kohlrabi are much neglected as fodder-crops, although they may be very conveniently grown, by planting them in rows between a corn crop. The corn protects the young plants, and when it is cut they occupy the whole ground. The cabbage plants are raised in seed beds and transplanted at the proper season; kohlrabi is sown in drills as turnips, and thinned out to one foot apart in the drill; the thinnings may be set out at the same distance. This latter crop does not impart a disagreeable flavor to the milk when fed to cows. Prickly Comfrey, at the North at least, is still a matter of experiment; the coming season should allow its value to be ascertained.

Root Crops for Stock.

BY PETER HENDERSON.

While "Mangels" and other roots for stock feeding have been largely cultivated in Europe, for the past 30 years, it is surprising how little it is yet done here, particularly when we know how well our soil and climate are, in most sections, adapted to the purpose, and how great are our necessities, particularly in those States, where the long dry summers diminish the crop of hay and other fodder plants. The most important root crop for stock is the mangel-wurzel, which, I believe, can be grown and matured in any good soil in any State in the Union. As with all root crops, a loose friable soil, with a sandy or gravelly subsoil, is better adapted to it than a stiff soil with a clayey subsoil. All root crops require deep culture; the soil should always be plowed to the depth of 10 inches, and, if it can be done, it will pay well to let the subsoil plow follow in the wake of the other, and stir the subsoil 10 inches more, making a loosened depth of 20 inches.

In many of our deep, rich, new soils, an excellent crop of mangels, or other roots, can be grown without manure; but when necessary to use it, nothing is better than well-rotted stable manure, composted with as much muck or turf from roadsides, spread evenly over the surface before plowing, at the rate of from 6 to 12 tons per acre; in absence of stable manure, bone dust, superphosphate, or guano should be applied, at the rate of from 300 to 500 lbs. per acre; but all such concentrated fertilizers should be sown on the surface, after plowing, and harrowed in, until thoroughly mixed with the soil. Before sowing, the ground should be

smoothed as evenly as possible with the back of the harrow, to present a smooth and level surface for the reception of the seed. The distance apart between the rows for mangels, will vary with the character of the soil. In light, sandy soils, the rows should be 24 inches apart, with 9 inches between the plants, but in strong, rich, deep soils, the rows should be 30 inches apart and 12 inches between plants. This is what is termed the "flat culture." Mr. Wm. Crozier, of Northport, L. I., works on an entirely different plan from this, and his success in producing enormous crops shows it to be well worthy of imitation. After thoroughly plowing, harrowing, and smoothing the land, he strikes out furrows with the double mould-board plow (if this is not obtainable, any plow that will make such a furrow will do), 30 inches apart, the furrow is 6 or 7 inches deep; these furrows are then half filled up with a compost made from stable manure and turf parings from the road sides, about equal parts, thoroughly mixed and decomposed, or if yet rough and unrotted, it is pressed down in the rows with the feet; after the manure has thus been placed in the furrows, the plow is run up between on each side, so as not only to cover in the manure, but to raise a ridge as high as the furrow was deep; these ridges are now run over with a roller or a light chain harrow, so as to take off or flatten down 2 or 3 inches of their apex, and so broaden the ridge as to allow the seed sower to work on it to deposit the seed. Where stable manure is not obtainable, Mr. Crozier recommends blood and bone fertilizer, or bone dust, sown in the furrows at the rate of about 300 lbs. to the acre, but where such fertilizers are used the ridge over the furrows should not be raised so high as over the manure. About 8 lbs. of seed is used to the acre, if put in with the "Planet," or other seed drill; when sown by hand, fully double that quantity would be required per acre. Mr. Megatt, the extensive seed raiser, of Hartford, Conn., recommends that, in using the seed sower, the hopper should never be more than two-thirds filled, and should never have any lid or cover, so that the operator can see its action, and should be shaken clear of all dust, as it accumulates, so that the seed may be evenly distributed. When the plants are up, they are to be thinned to 12 or 14 inches apart, and the land is well cultivated, so that before the crop covers the ground the ridges have been so levelled down that the rows of roots are nearly as low as the spaces between.

This ridge system of culture, both for mangels and turnips, although it requires more labor, is a saving in manure, and there is no doubt that these crops are greatly benefited by having the soil gradually taken from the ridge by the cultivator, and exposing their roots, or "bulbs," to the air. The best time for sowing, in the latitude of New York, is from May the 1st to the 15th. The time must, of course, be varied according to locality; probably the best guide in all sections, is to sow from 8 to 10 days before the time that corn is usually planted. The varieties most used are: "Webb's Mammoth," and "Norbiton Giant," (red varieties), and the "North" and "Kinver Globe," both yellow kinds. The average weight of the crop of an acre in mangels is 40 tons; though, in some soils, they have yielded double that weight. Of course their cash value, as compared with hay, (rating hay at \$15 per ton), will vary largely under different circumstances, but Mr. William Crozier considers that the average value of mangels for stock feeding purposes, to be \$4 per ton, or \$160 per acre. While hay would be, under the same condition, (estimating 2 tons per acre), only worth \$30 per acre, the expense of seed, manure, and cultivation of the mangels, at the utmost, need not exceed \$80 per acre, so it is clearly seen that the crop for feeding purposes is a profitable one. What has been said on the modes of culture for mangels, may be applied

To Turnip Culture.

except as to the time of sowing. The Swedish or Ruta Baga varieties of turnip, should be sown, in this latitude, from May 25th to June 25th, and the Yellow Aherdeen and Strap-leaved kinds, from July 1st to the middle of August. When sown at these dates, the distance apart may be the same as for mangels, but both of the classes may be sown a

month later—that is, the Ruta Bagas may be sown from June 25th to July 25th, and the Strap-leaved kinds from the middle of August to the middle of September, but, when sown thus late, they should be both between rows and between plants, one-third closer. The varieties that we find best, are “American Ruta Baga” and “Purple-top Ruta Baga;” of the Strap-leaved kinds, “Red-top Strap-leaved” and “Yellow Aberdeen.” Mr. Crozier’s estimation of value of Ruta Bagas, as compared with hay, (at \$15 per ton), is \$5 per ton; average crop, 25 tons per acre, or \$125. Purple-top Strap-leaved, or Yellow Aberdeen turnips, he estimates at \$3.50 per ton; average crop, 35 tons per acre, or \$122.50. Estimating the expense of culture at half the gross value, we have still a large margin in favor of the crop; besides the Strap-leaved turnips can be sown after barley, oats, or rye.

Carrots may properly come under the head of “Root Crops for Stock,” though mainly grown for horses, but, even for horses, Mr. Crozier says that he considers them far inferior to Ruta Baga turnips. This is in opposition to the received notion, but we know that public opinion in matters of this sort is often wrong, and when we consider the marked success of Mr. Crozier, as a raiser of both horses and cattle, his opinion in this matter is entitled to consideration. The land for carrots should be prepared exactly as for mangels; it must be deeply plowed, harrowed, and thoroughly pulverized, and whatever kind of fertilizing material is used, it should be thoroughly mixed with the soil to a depth at least of 10 inches. The same quantity and kinds of fertilizers should be used as recommended for the flat culture of mangels, though in new lands, or lands on which corn has been grown after sod, enough of the fertilizing material will usually be left in the soil to mature a good crop of carrots without any manure, provided the soil is deep and in good condition. I once grew 20 tons of carrots per acre on land in this condition, without using a particle of manure. Carrots should be sown from the 1st to 30th of May, and when sown by a seed drill, about 4 lbs. of seed to the acre is required. The rows should be 2 feet distant, and the plants thinned out to 5 or 6 inches apart. An average crop is 15 tons, of the “Long Orange” variety, to the acre, and the present price averages \$15 per ton in New York market. The “White,” or “Yellow Belgian” Carrots would give one-third more weight, but the quality is inferior and the price correspondingly lower. One of the seeming obstacles to raising root crops on a large scale is the lack of a proper place for keeping them in winter.

Keeping Roots in Winter.

A general impression prevails that they must be kept in cellars or in a root house specially built for the purpose. There is not only no necessity for a special root house, as the simple and cheap method of preserving them in pits in the open ground is far better. I will briefly describe our plan, which I have practised with all kinds of market garden roots for 25 years. Mangels, in this section of the country, are dug up towards the end of October, or just after our first slight frosts; they are then temporarily secured from severer frosts by placing them in convenient oblong heaps, say, 3 feet high by 6 feet wide, and are covered with 3 or 4 inches of soil, which will be sufficient protection for 3 or 4 weeks after lifting, by that time, say the end of November, they may be stowed away in their permanent winter quarters. For turnips and carrots, there is less necessity for the temporary pitting, as they are much harder roots, and may be left in the ground until the time necessary for permanent pitting, if time will not permit to secure them temporarily. The advantage of this temporary pitting is, that it enables them to be quickly secured at a season when work is usually pressing, and allows the period of their permanent pitting to be extended into a comparatively cold season; this is found to be of the utmost importance in preserving all kinds of roots—the same rules regulating the preservation in winter, apply as in spring sowing; while in this section of the country it must be done not later than the end of November; in some of the Southern States, the time may be extended a month later,

while in places where the thermometer does not fall lower than 25 degrees above zero, there is no need to dig up any of these roots at all, as that degree of cold would not injure them. The permanent pit is made as follows:—A piece of ground is chosen where no water will stand in winter. If not naturally drained, provision must be made to carry off the water. The pit is then dug 4 feet deep and 6 feet wide, and of any length required. The roots are then evenly packed in sections of about 4 feet wide, across the pit, and only to the height of the ground level. Between the sections, a space of half a foot is left, which is filled up with soil level to the top; this gives a section of roots 4 feet deep and wide, and 4 feet long, each section divided from the next by 6 inches of soil, forming a series of small pits, holding from 6 to 12 barrels of roots, one of which can be taken out without disturbing the next, which is separated from it by 6 inches of soil.

Scotch Method of Wintering Roots.

Mr. Crozier practises with great success the Scotch method of preserving root crops in winter, which he thus describes: A dry spot being selected, where no water will stand in winter, a space is marked out 6 feet in width, and of any length required; this bed is excavated 10 to 12 inches deep, and the soil is thrown out on the bank. The roots, either mangels, turnips, carrots, or potatoes, are built up evenly to a sharp point about 5 or 6 feet in height, so that the roots form almost an equal sided triangle, 6 feet on the sides. This bed of roots is then thatched over with 4 inches of straw, after which the earth is banked over the whole, about 1 foot in thickness. This covering of earth and straw is sufficient to keep out any degree of frost that we have in this latitude, though we rarely have it much below zero, in colder or warmer sections, judgment must be used to increase or lessen the covering. Vents, or chimneys, made by a 3-inch drain-pipe, or anything of similar size, are placed every 6 or 8 feet along the top of the pit, resting on the roots, so that the moisture generated may escape. In extreme cold weather, these vents, or chimneys, should be closed up, as the cold might be severe enough to get down to the roots. Pits, so constructed, rarely fail to preserve roots perfectly, until late in spring, and are in every respect preferable to root cellars. For no matter how cold the weather may be, they are easily got at; the end once opened, the soil forms a frozen arch over the pit. Mr. Crozier says he has practised this plan for years on his farm at Northport, L. I., some of his pits containing hundreds of tons of mangels, etc.

How to Use Artificial Fertilizers.

In using strong chemical fertilizers, it is necessary to remember that 100 lbs. of such a mixed fertilizer as Ville’s “Complete Manure,” as compounded by the Mapes Formula Company, contain very nearly as much of the useful chemical elements as one ton of ordinary manure, and further, that these elements are in a directly active and soluble state. If, in applying these fertilizers, we should place them in contact with the seed, the young germ would be fatally injured, and the plant destroyed before it could appear above ground. To prevent this danger, all these concentrated fertilizers should be thoroughly mixed with the soil before the seed is sown, or young plants are transplanted. Our own practice is as follows. For wheat, rye, or other similar crops, the fertilizer is spread in the fall, immediately before the seed is sown; the seed is then sown and both are harrowed in together. In spring we sow the fertilizer upon the surface, and either leave it to be carried in by the rains, or we harrow it in, when we harrow the wheat or rye, with a light, sloping-tooth harrow, such as the Bradley reversible or the Thomas harrow. For corn we scatter a portion of the fertilizer along the rows as soon as they are marked out; it is then well mixed with the soil in the process of planting and covering, and while it is near the seed, it is not in direct contact with it, except in very small quantities, which are thoroughly incorporated with the soil. Afterwards, when the corn is hoed, a second

portion of the fertilizer, say 100 lbs. per acre, is scattered along the drills or hills, on each side of the plant a foot or so distant, and then the crop is cultivated or hoed. For field crops of vegetables that are transplanted, such as cabbages or tomatoes, we apply the fertilizer on the harrowed ground as soon as it is marked out, and when setting out the plant, the soil and a part of the fertilizer are mixed together. Afterwards the remainder is given at the first cultivating or hoeing, as for corn. By such methods as these, the young and tender roots are not brought into close contact with the concentrated chemicals of which the fertilizers consist; but they are fed gradually as they reach these in their growth, or as these dissolve and are carried down to the roots by the rains. Lastly, it is well to give the caution, not to leave the fertilizers about where poultry, sheep, or other animals, can pick up fragments or lick the bags; nor to wash the bags in water-troughs, streams, or ponds, where animals drink, as some of the chemicals are poisonous.

POPULARITY OF THE AYRSHIRES.—As a sign of the returning popularity of the valuable Ayrshire cattle might be cited the fact, that at the fair of the New York State Agricultural Society, the Ayrshires outnumbered the heretofore preponderating Jerseys. The Ayrshire, as a butter-making breed, is hardly a rival of the Jerseys; these two should be companions, and not rivals, for each one has invaluable points. A fact of curious significance also, at this fair, was the absence of several of the old successful show-herds, and the entry of new exhibitors, who carried off the honors. It is further worthy of remark that, with all our success in breeding excellent animals, our prize-takers are too frequently imported. Would it not be well to keep prizes only for native bred animals?

IS MACHINERY PROFITABLE?—The grand display of agricultural machinery at the New York State fair at Rochester, in September last, not only attracted much favorable notice from farmers, but also some adverse criticism from other persons with little experience in the use of machinery. The question often arises, “is it profitable to use machines in place of hand labor under all circumstances?” To this might be replied, very decidedly, that it is not. There are some cases where hand labor is more profitable; for instance, a farmer who has nothing to employ his time during the winter, may better use the flail to thresh his grain, than to hire or own a threshing machine to do the work. Although in this case the threshing might cost five times as much in labor and time, yet here time is not money, or at least it may appear that the old adage is at fault for once. But beneath this circumstance even, there lies a mistake. This is, that no farmer should find his time so valueless, that he can afford to spend it in earning 50 cents or less a day, (which is what it costs to thresh 10 bushels of grain with a machine,) and it is a mistake to manage his business so that he has nothing else to occupy his time. This is the principle that should lie at the bottom of this question of the value of machinery. Every man should so arrange his business that “time is money” to him, and if he can save time by using a machine of any kind, then he saves money, and its use is profitable.

FEEDING FOR MILK.—“Litchfield.” The most economical food for milk cows is a mixture of hay, meal, and bran; and the most economical way of feeding these is to cut the hay, moisten it, and sprinkle the meal and bran over it. This gives some trouble, but it pays. From our own practice, we believe 25 per cent of the feed is saved. One bushel-basket of cut hay, and 2½ quarts of corn meal and bran, mixed in equal portions, is a feed for a cow in good milk. To some cows more of the meal and bran may be given profitably; this must be found by testing the different cows. The above feed is for half a day—that is, is given twice in the day, making 5 quarts of the meal and bran daily. In addition to the above feed, a few pounds of dry hay, or some roots, may be given at noon.

The Use of Corn for Fuel.

Some journals, whose conductors know very little about corn growing, and other things in the

Fig. 1.—PERSPECTIVE VIEW OF LIVERY STABLE.

West, make their annual outcry in regard to the extensive consumption of corn for fuel, which they consider a great and inexcusable waste. Suppose the Nebraska or Minnesota farmers were to sell two tons of corn for six dollars, and buy half a ton of coal for the money, and the corn were at once taken to a distillery and turned into whiskey. Would this be any better? The farmer would probably have to make two journeys of 10 or 20 miles each, with his loads, and be out of pocket at least \$6 by his trade. The fact is, corn is an excellent fuel, and although it may seem at first sight to be wrong to burn up an article of food, yet it is but a mere sentiment which overlooks the fact that to warm one's self by a fire, and to do the same by the consumption of food, are in the end precisely similar in effect. If more warmth can be procured by consuming, in a stove, a dollar's worth of corn, than a dollar's worth of coal, it is a legitimate use for the corn; but when there is neither coal nor wood at hand, what should these people do when the winter's cold pinches, if the corn from their well-filled cribs could not supply them with fuel?

A Plan for a Livery Stable.

At the present time, when economy must be strictly observed by many persons whose income

Fig. 2.—PLAN OF STABLE.

is reduced by reverses, or lessened profits of business, the livery business is increasing its extent. Many who have hitherto kept carriages and horses, have been obliged to give them up, on account of the expense, and to hire them from a livery stable

Fig. 3.—TROUGHS.

when occasionally needed. This has resulted in a greatly increased demand for hired horses and carriages, which shows itself in the curious way, amongst others, of inquiries made of us about building and furnishing livery stables. The essential needs in a livery stable are: a convenient arrangement for stalling the horses, and for storing away the carriages. There must be means pro-

vided for perfect cleanliness, as nothing injures a carriage more quickly than the ammoniacal vapors from a foul stable. A proper arrangement for cheapness and convenience would be as follows: The building should be from 25 to 36 feet wide, ac-

ording to the ground that can be spared for it, and as long as necessary to accommodate the number of horses to be kept, allowing 5 feet for each single stall. Generally, it will be found best to build so that additional length can be added, as business increases. The inside arrangement is as shown at figure 2. The office is placed at the entrance upon one side. Opposite, is the pump and water-trough, this trough is connected by pipes with each feed-trough, one end of which is made water-tight and separate for water. The connections are made as shown at figure 3; *a* being the water-trough, *b*

the watering boxes for two adjoining feed-troughs, both being supplied by one inlet pipe. The pipe goes through the stable and has a cock beneath the water-trough, by which the water-boxes are drained into the sink. The pump should be one that can be used either for a force or a suction pump, so that, by means of hose, the water can be carried to any part of the building. Along the center, is a row of trap-doors, through which the manure and drainage of the floor are dropped into the cellar. Alternating between the doors, are posts furnished with hangers, upon which the harness is suspended. Opposite to the horses is the space for carriages. This is provided with shallow gutters, to drain the water from the washing into the trap-doors and the cellar. In front of the horses, is a row of small windows, one for each stall, provided with lattice shutters, sash, and fly-proof netting, so as to give plenty of ventilation, but only moderate light. These should be above the horses' heads and near the ceiling. The hay and feed bins should be kept above, and spouts provided to drop the feed into each trough below. That no hay or other matter may enter the water-pipe, the inlets are covered with mushroom strainers. At figure 1 is an elevation of the building.

A Combined Carriage and Tool House.

A number have asked for a plan of a carriage, wagon, and tool house in one building, suitable for a large farm. The accompanying engravings give a plan for such a building, with a granary above. The structure may be 16 or 18 feet high to the eaves, which will give a space of 9 feet in the clear for the lower story, and 6 feet in the clear for the granary at the walls, and 10 or 11 feet in the center between the bins. It should be at least 24 feet wide, and 45 feet long, to give ample space for moving about in it. The wagon and cart house would be at one end, and 24 feet square, shown in the plan (fig. 1), to contain three wagons and a cart. The doors of this portion slide upon

rollers, and, to facilitate the movements of the wagons in or out, are in three divisions. The carriage house is in the center, with the entrance at

Fig. 1.—PLAN OF WAGON HOUSE.

the front. Here is room for two carriages, and a tool house adjoining, with entrance at the end opposite to that of the wagon house. In the carriage house there should be a well and a force pump furnished with a hose, for the purpose of washing off

Fig. 2.—PLAN OF THE UPPER FLOOR.

the carriages, and the floor should be made slightly sloping each way to the center, with a gutter there to carry off the water to the rear. One of the Blunt's "Universal Pumps," made by the Nason Manufacturing Co., of New York, would be most useful for this purpose, being the most easily worked, and the most effective of its kind that we know of. It is either a force pump or a draw pump. If it would be more convenient to have the pump outside of the building, one of the "Standard Non-

Fig. 3.—VIEW OF COMBINED WAGON AND TOOL HOUSE.

freezing" out-door pumps, of the same makers, would be found useful, either in winter or summer. In case of a fire among the buildings, the pump would be found of the greatest value. The upper floor may be reached by a stairway outside, or from the inside, as may be most convenient. The plan of the bins is given at figure 2. On one side are the three grain bins, and on the other, two lathed bins for corn in the ear. Between these is the hoisting wheel and door; the plan of the hoist is shown at figure 4; *a* being the winding barrel, *b* the pulley wheel, with an endless rope hanging upon it, and *c* the pulley in the cat-head. The hoist is supported by hangers fastened to the roof timbers and the plate. Figure 3 is the elevation, which may be changed to suit the wishes or the means of the builder. Here it is made perfectly plain, in order to meet the wishes of the most economical.

Fig. 4.—HOIST.

The Common Reed.—*Phragmites communis*.

The most stately and conspicuous native grass of the Northern States is the Reed. It is also one of the most widely distributed, as it not only extends completely across this continent, but has an equally wide range in the Old World, from the tropics to

purpose, and they are sometimes used for the construction of huts. Excellent sereens, or mats, for garden purposes, are made by placing the stems side by side, and interlacing them at the ends with osiers. The Swedes are said to use the panicles to make a green dye for woolen stuffs. Like many other plants which naturally grow in wet places, the Reed bears removal to the drier soil of the gar-

naus, and is borne by two native species of shrubs or small trees, and by a third, found in Japan. Belonging to the same family with the Camellia, and the Tea, they have a general resemblance to those well known plants, though in the case of the *Stuartias* the leaves are deciduous. That such showy plants should not have received a common name, is probably due to their comparative rarity in the

THE COMMON REED.—(*Phragmites communis*.)

THE STUARTIA.—(*Stuartia pentagyna*.)

the arctic zone, and even occurs in Australia. It is found in swamps and marshes, and along the edges of ponds, sometimes reaching the height of 12 feet, and having, at a distance, much the appearance of Broom Corn. In less favorable localities, it grows to only 5 or 6 feet, and we have seen it flower when only two feet high. The leaves are numerous, on large plants about two inches wide, and the stem is terminated by a large, soft, purplish panicle of flowers, which usually gracefully bends to one side, and is from a few inches to one or two feet long. The individual spikelets are from $\frac{1}{4}$ to $\frac{3}{4}$ inch long, and each contains three to six flowers; the lowest one is staminate, or neutral, while the others are perfect; the little stalk which supports the florets is furnished with very long and silky hairs. The engraving gives the general appearance of the flower cluster or panicle, though reduced in size, and below is a separate spikelet, about twice as large as natural. The plant has numerous strong underground stems, or root-stocks, which extend in all directions, and have been known to reach the length of 40 feet; these make the Reed a most serviceable plant in securing the banks of rivers, as by their interlacing they bind the soil and prevent washing; it has also been planted to aid in the reclamation of low lands. The foliage is eaten by cattle when it is very young and tender, and then only when other food is scarce. In Northern Europe the stems are used for thatching; they are regarded as the most durable of all materials for the

den, and may be used in contrast with *Arundo Donax*, *Erianthus*, and other large ornamental grasses. In the present popularity of grass bouquets, the Reed has been used in large quantities. When dry, the spikelets open, and expose the silky hairs, which are so abundant that the panicle has a very different appearance from that it presents when growing. For this purpose, the panicles should be gathered when they are in flower, which will be known by the presence of stamens, as in the spikelet at the lower part of the engraving. If left until the seed is ripe, or even partly developed, the spikelets are apt to break apart and shed their down in an annoying manner. Formerly this was placed in the genus *Arundo*, and in some of the European works of the present day it will be found as *Arundo Phragmites*, but the name generally accepted is *Phragmites communis*, as the structure of the flowers is essentially different from those of the *Arundos*. The name *Phragmites* is from the Greek, meaning "growing in hedges," the application of it to this plant is obscure, as it is not a hedge-plant.

Fine Ornamental Shrubs—The Stuartias.

The indifference of Americans to beautiful native plants, is nowhere more strikingly shown than in their almost entire neglect of the Stuartias. The genus was dedicated by Catesby to John Stuart, Marquis of Bute, who was a correspondent of Lin-

wild state, but this is the less to be regretted, as *Stuartia* is a pleasing name, and, like *Magnolia*, may well serve in both botanical and popular nomenclature. Our two species are, *Stuartia pentagyna*, (the Five-pistilled Stuartia), found in the mountains of Tennessee and Virginia, to those of North Carolina and Georgia, and *S. Virginica*, (the Virginian Stuartia), which extends from Virginia to Florida, and westward. The first named is the showier as well as the hardier of the two, and is the one offered by a few of our nurserymen. This, *Stuartia pentagyna*, has a bushy habit, and ultimately forms a dense clump 10 to 15 feet high, and as much in diameter. It has oval, pointed leaves, usually with minute teeth on their margins, and downy on the under surface. The flowers, from the axils of the leaves, on very short stalks, are two and a half inches, or more, in diameter; the calyx is covered with silky hairs, and often tinged with red. The petals, usually five, but sometimes six, are cream-colored, sometimes purplish at the base, and beautifully scalloped or crimped on the margins; the stamens are numerous; the pistil has five distinct styles, and ripens into a woody, ovate, pointed 5-celled pod, with one or two seeds in each cell. The other species (*S. Virginica*) differs from this in having downy leaves, smaller, white flowers, and purple stamens; its styles are united into one, and the pod globose. It is less hardy than the other, and probably can not be depended upon north of Philadelphia. The first named species, *Stuartia*

pentagyna, is quite hardy in the vicinity of New York, and, if we mistake not, in the neighborhood of Boston also, but does not prove hardy at Rochester, N. Y. Wherever it can be grown, there is no more desirable shrub, as it is handsome for its foliage alone, and when covered with its large flowers, like a single *Camellia*, it is one of the most beautiful of all flowering shrubs. The engraving gives the appearance of a single flower—though somewhat reduced in size, and the form of the leaves, but of course fails to give the effect of a large shrub, loaded with flowers of this kind. Another point in favor of the *Stuartia*, is the time at which it flowers; in August, when the earlier shrubs have quite finished blooming, and before the later flowering ones appear, this comes with a most welcome profusion of flowers. This shrub has two faults; it is native, and a good specimen can be bought for a dollar. Were it Japanese, and sold at \$5 or \$10 a plant, it would probably be much more sought after. Several years ago, the Messrs. Parsons, of Flushing, N. Y., knowing the real merits of the *Stuartia*, were at much trouble and expense in sending a collector into the mountains of the Southern States, who procured a large stock of it. The Messrs. Parsons & Sons Co., of the Kissena Nurseries, Flushing, N. Y., inform us that their large stock is especially fine, it having been several times transplanted. We know of no shrub more attractive in a collection, or which is more worthy to stand as a single specimen than this *Stuartia*—in all localities except those in which the winter is very severe. Those who wish a single shrub to ornament a city front yard, may properly select this, as it will be in full bloom at midsummer, when their neighbor's plants are quite without flowers.

Propagating Plants from Leaves.

That plants may be propagated by cuttings is well known, as few persons, who have cultivated flowers at all, have not grown a rose or a geranium from "a slip," which is the popular name for what gardeners call a "cutting." But that some plants may be propagated from their leaves, is new to many. One plant, *Bryophyllum calycinum*, popularly known as the "Leaf Plant," was figured in June, 1876. The leaves of this, when they fall to the ground, form small plants from the notches on their edges. Several plants are regularly propagated by florists from leaf cuttings. A number of the showy plants of the *Gesneria* Family are multiplied in this manner, as are all of the *Begonias*, of

gate them, the florists put a leaf on the sand of the cutting-bench, and make several cuts through its numerous strong veins. After a while buds appear at these wounded places, and these develop into plants, as shown in the engraving, from a leaf furnished by Peter Henderson, Esq. Some florists cut the leaf into little pieces, which are laid upon the sand, and produce the same results. Those who wish to try this method of propagating, should take care to give the leaves proper shade, else they may dry up before forming roots. Many other plants have been propagated from the leaf, including the orange and the rose. But, besides for certain *Begonias*, it is employed, in a practical way, on a number of the succulents, such as *Echeverias*, *Kleinias*, *Paehyphytums*, etc. The well-known method of propagating lilies, is really propagating from the leaves. The fleshy scales of the lily bulbs, which are broken off, and treated as cuttings, are only the thickened bases of the lily leaves, and though their upper green portion has dried away, the scales are really leaves. No doubt the number of plants that may be multiplied from leaf-cuttings, may be largely increased, and it offers an interesting field to those who wish to try experiments.

A DANGEROUS PET.—Several of the English papers have given accounts of a remarkable parasite which, in the Glasnevin (Scotland) Botanic Gardens, has adorned the stems of a *Forsythia*, "with a dense entanglement of pearl-colored, Lily-of-the-Valley-like flowers, smelling as sweetly as a *Heliotrope*," and much more in the way of enthusiastic description; after this we are told that the plant is one of our American *Doddies*, *Cuscuta Cephalanthi*—the correct name of which, by the way, is *C. tenuiflora*. We should think that English cultivators had had sufficiently disastrous experience with their *Clover* and *Flax* *Doddies*, to make them cautious how they naturalize this larger-flowered and more showy American species. Should this become established, it may prove as undesirable in their plantations as our *C. compacta* is with us. This, in some of our nurseries, has proved to be a real pest, attaching itself to and living upon the young stock, and exhausting it much to its detriment.

Forwarding Lettuce—A New (?) Way.

BY PETER HENDERSON.

The other day, in riding out on the N. J. Central R. R., I had occasion to go a short distance across the country, south of Plainfield. I noticed an old

colored man digging parallel trenches 2 feet apart, about 6 inches deep, and 10 inches wide. He had just completed about a dozen of them some twenty feet in length, and had begun to scatter manure in the bottom of the trenches to be dug in. I was completely puzzled by the operation; he was evidently at some kind of gardening, but such trenching, in the middle of February, I could not understand. On questioning the old man, I found that these were his forcing pits for Lettuce—which he planted 6 inches apart in the trenches, and covered up at night and in cold days with single boards a couple of inches

wider than the trenches. This method, he assured me, he had practised for many years, getting his lettuce two or three weeks earlier than when planted without such protection. He was careful to take off the boards and expose the plants to the light on mild days. His "frame

ground" had been well chosen, it being a sheltered, rather sandy spot, facing the south. I suggested to him that his "pits" might be used for protecting tomato plants, after his lettuce was cut, but Sambo had nothing to learn from me; he had always used them for that purpose, only digging his trenches deeper; and had raised, he said, the best "tomatoes" in the neighborhood, from plants set out in his trenches about May first, after his lettuce had headed up. Sambo's forcing pits were not extensive—they only held about 600 lettuce plants; but these brought him five cents a piece at the village groceries, and it was certainly a productive industry in a small way that is worthy of imitation.

The Catalpa and Its Uses.

Prof. C. S. Sargent, Director of the Arnold Arboretum, takes a lively interest not only in trees as trees, but also in their uses; thinking that the merits of the *Catalpa* had been overlooked, he was collecting materials for an article for the *American Agriculturist*, when he came across a pamphlet entitled: "Facts and information in relation to the *Catalpa* Tree, (*Catalpa bignonioides*). Finding his proposed task so well done by the author, Prof. Sargent, in the following note, gracefully gives full credit to another worker in the same field. He says: "Mr. Barney has brought together, in a pamphlet of 26 pages, (which may be procured from the author, E. E. Barney, Esq., Dayton, Ohio,) several letters contributed by him, at different times, to the "Railway Age," in regard to the *Catalpa*, to which are added much testimony and information in regard to its economic value. By what must seem most satisfactory evidence, it is shown that the wood of the *Catalpa*, although soft and comparatively light, possesses, to a remarkable degree, the power of resisting decay, in this particular equalling and even surpassing the *Locust*. He claims that for rail-road sleepers, the wood of no other tree, which has yet been tried for the purpose, compares with it. The qualities which make a tree profitable to raise for sleepers are: that it should grow rapidly and easily; that its wood should be durable when exposed to the weather, and neither too hard to properly hold spikes, or too soft to resist crushing by the pressure on the rails. These qualities, Mr. Barney proves, are combined in the *Catalpa*; and his pamphlet, containing also many excellent cultural suggestions, is a welcome addition to the arboricultural literature of the day, and should be circulated among all who interest themselves in our forest economy, and the railroads of the far West."

One Grape Vine.

FIRST ARTICLE.

We can not conceive of a place, unless in a tenement house in a crowded city, where one can live, and not have room for at least one grape vine. Most of those who live in villages, have room for several vines, and those who live on farms have room for all the vines they care to plant. Several years ago we had occasion to call upon a distinguished general of the U. S. Army, who was stationed in New York City. Our business over, he took us into his back yard, probably 25 by 50 feet. We found along the fences some 8 or 10 grape vines, all properly labeled. We asked for how long he had taken the house. He informed us, for a year, but was liable to be ordered off at any time. We remarked that he could get no returns from his vines until the next year. He replied that he was well aware of that, but he made it a rule, wherever he went, to plant vines, for, he said, "somebody will get the fruit from them." We had heard of this officer's heroism when on the staff of Gen. Scott, in the Mexican war, but this remark, "somebody will get the fruit from them," showed him to be a good as well as a great man. "Why do people have so few grapes?" is a question that has often puzzled us. Go over the country, and we find the farms that have an abundance of grapes are few, while those who have none are in the majority. Those who live in towns and villages, with

LEAF OF BEGONIA WITH YOUNG PLANTS STARTING FROM IT.

which *Begonia Rex* is the type. *Begonia Rex*, and its varieties, are among the most showy of greenhouse plants, as their foliage presents a great variety of color, and they are much used for greenhouse and conservatory decoration. Their leaves are large, and have very strong veins. To propa-

but a few feet of land, will have grapes in abundance, while those who have 50 or 100 acres, or more, are without this welcome fruit. Why is this? It certainly can not be the cost, for 25c. to 50c. is the average price of vines. We think it is from some feeling that vines are difficult to manage, that there is some "mystery" about pruning that they cannot master, that prevents the general planting of vines. Now we advise every one who has the land—and if that is but 10 feet square, it will hold several vines—every farmer, who would provide his family with this most acceptable fruit, and, we may add, would increase the attractions of home, to plant out grape vines. It must be a strange farm that can not find a place for them, as we have over 50 vines in a space 200×100 feet, and all in full bearing. There is nothing about the vine, its training and pruning, that any one can not understand. We head this article "One Grape Vine," because what may be done with one vine, may be done with five, or fifty, or more. The first question will be,

What Kind Shall I Plant?

As a general thing, if one knows nothing about vines, and is to put out but one, we say plant a "Concord." But we do not advise any one who has the room, to restrict himself to one, so we add as a list to choose from, Delaware, Creveling, Hartford Prolific, Barry, Wilder, Brighton, and Eumelan.

Fig. 1.—VINE AS RECEIVED.

These are all good, as family grapes, though not equally good market sorts, and are generally successful. Now, when you order a vine from a nursery,

What do you Get?

If the nurseryman understands his business, you will get—not a big vine—but a copious root, with a stem having, perhaps, three or four buds upon it. When you get the vine or vines, make the soil mellow—never mind manure now—open a broad hole, spread the roots, and cover them about 4 inches deep. But, before setting the vine, put down a stake, about 6 feet high, and plant the vine with the stem close to the stake. Spread the roots well, have them covered with the best of the top-soil,

Fig. 2.—PLANTING THE VINE.

and when covered, press down firmly with the foot. Now, what have you got? You have the roots well planted, and a dead-looking stem, with 3' or 4 bunches along it, as in figure 1. These bunches on the stem are buds, and the growth of the vine will start from them. Watch them well. You will find, perhaps, that the uppermost swells and breaks first, then the next below will break, and after that the others. The first thing to do is to rub off all but the two best and strongest of the buds, and when the uppermost, or the next below it, has made a shoot long enough to tie to the stake, tie that to the stake with a piece of soft cotton twine, bass matting, or whatever will hold it without cutting. And then break off the other shoot—you will hate to do it, as

it looks so promising, but the only way to start right, is to grow but one shoot the first year, and to keep that tied up to a stake as it grows. Certainly there is nothing difficult about this, and whoever does it, with one vine, or one hundred, will have made a fair start. Let the vine grow, keeping it tied up, and later, we will tell what to do with it.

Where to Plant Vines.

Anywhere, where there is six square feet of soil. They may be trained to special trellises, and this is necessary where there are many, but a vine may be trained to a fence, to the side of a shed, or a barn, or to the dwelling house. Once understand the manner of the growth of the vine, and it may be put almost anywhere.—How the vine grows, we shall try to show in other articles. In this we insist upon planting, at least *one vine*, but hope that those who have the room will plant many more, and we also insist that the vine shall be treated properly, and be allowed to form but a *single shoot* the first year. An old vine with several feet of stem and little root is not worth planting by any one.

About Irrigating our Gardens.

The sight of the wonders wrought by irrigation in Colorado and California, some years ago, stimulated me to try the experiment, on a small scale in a new garden, for the last two seasons. I came into possession of an old gravel pit, upon a side hill, covering about three-fourths of an acre. The soil in the highest part of the lot had been removed to the depth of twenty feet or more, some twenty years ago, for the purpose of making wharves in the village. Nothing was left but hard-pan and gravel. In the bank a spring had been struck, where the water oozed a little, all summer, and run a small stream during the winter. The surface soil below had never been planted, and bore nothing but coarse grasses and weeds. A part of it was deep mire in winter, and not dry enough to plow in spring until late in May. A more unpromising piece of land for a garden could hardly be found. Tiles were laid to the depth of three feet, completely removing the surface water, and making early plowing practicable. Being without stable manure at the time, I used coarse sea-weed to turn under and loosen the soil, and applied a compost of fish-scrap and soil, in the hill. The yield of corn, potatoes, cabbages, and turnips, was much better than could have been expected. The soil improved every year, and the crops grew better. Two years ago I thought of turning the spring to practical account for irrigation. It had been previously cleaned out and deepened, and a pool about ten ft. square had been walled in, to furnish a small pond for ducks, and also to convey water to the hen-house. The waste-water, which would not more than fill a half inch pipe in summer, ran off into the tile-drains and benefited no one. On the driest part of the gravel bank below, squashes and melons were planted. A few troughs of hemlock slats were made, and the water was put on to the melon-patch early in July. After the vines were well started, the stream was kept in one place for a day or two, until the ground was thoroughly soaked, and then changed to other hills, until the whole patch had been irrigated. Although the soil was poor, and the only manure was that in the hill, the growth of vines was luxuriant, and there was a very fine crop of nutmeg and water-melons. Owing to the depredations of the bugs, the squashes did not succeed so well. Last summer the experiment was repeated with still better success. In hill-countries, like many parts of New England, there are thousands of places, where gardens and fields can be irrigated from surface streams, at very small cost, and thousands more, where wells and wind-mill pumps would make water available for the garden. We may safely calculate upon doubling our crops by the timely supply of water through the growing season. It would be a complete safeguard against drouth, and would be helpful every season. Water enables the plant to make the best use of the manure given it, and to get large supplies of food from the soil.

BY FAITH ROCHESTER.

After the Kindergarten.

Some good soul—a reader of this journal, I fancy—has sent me a few numbers of the new "Primary Teacher." In the second number is an article by Mrs. Hopkins, giving an account of one year of her teaching in a city of Massachusetts. I read this article with the greatest delight, and have re-read it about a dozen times. I want to copy every word of it here, but of course that would never do. Besides, I have become aware that this very article awakened quite varied sentiments in different readers. Colonel Higginson sent it to the "Women's Journal," recommending its perusal to teachers and mothers. This has called out some responses from teachers, who express themselves shocked by the amount of learning accomplished by Mrs. Hopkins' pupils. Let me see if I can tell briefly some of the work done in her little private school of girls from eight to fourteen years of age. The only previous education of the younger ones had been a good Kindergarten. They got quite a clear vision of the course of events in this country for 200 years past, from Higginson's "Young Folks' History," went through Dickens' "Child's History of England," and had the prominent points of Greek and Roman Mythology from reading "The Age of Fable." They reviewed Miss Hall's "Primary Geography," which had been read to them in the Kindergarten, then took the higher geography and went nearly through the geography of the United States. After some language lessons, they found to their joy that they knew grammar already, so they left that to take care of itself, and went on to dictation exercises and composition. Reading and spelling they learned by having constant exercises in one way or other.

It was found necessary to restrain their excitement, somewhat, in the mental exercises of arithmetic, though they had frequent exercises, and became very quick and skillful in rapid calculation. They studied the fundamental rules, applying numeration to fractions, decimals, U. S. money, compound numbers, the metric system, etc. All these were treated as varied applications of the simple rules of numeration, addition, and subtraction.

They learned also from Prof. Gray's "How Plants Grow," and Miss Youman's little Botany, (at least they learned on her plan), analyzing flowers readily, and enjoying much of the higher and more delightful developments of botany. They studied the forest trees by walks in the woods, and reference to Mr. Emerson's book. They learned what Morse could tell them in his "First Book of Zoology," Mrs. Agassiz, in her little "Sea-shore Book," and read together other books on land snails, butterflies, and other insects. They learned from books and pictures about our native birds. They had a teacher for drawing, and a French woman to talk French with them, learning by heart a few fables, and playing a French game with their teacher. They studied German in much the same way, reading at last with delight "Grimm's Tales" in German.

All this was done in one school year by children averaging ten years of age, though some had entered their teens. There was no constraint, no emulation, no rule of morals or manners, except such as they saw to be the necessary conditions of attentive study and good manners. Mrs. Hopkins hoped in the following year to advance her pupils as much in love of study, desire to learn, development of their faculties, and attainment of knowledge, as she felt had been done in the past year.

What is Said on the other Side.

Those who criticize this article protest against such "pouring into" the minds of children, suggesting how difficult it is to battle with the natural tendency of such children to distraction and thought-wandering. They forget that the younger ones of Mrs. H.'s class were trained in a Kinder-

garten, and as she says, "of course they were wide-awake and fresh for study." I know myself the difference between reading aloud in the family to children who are accustomed to pay attention, who delight in the reading selected for them, and to children who are not accustomed to such experience, and who distract others and look about for something to play with while I read. The work accomplished in Mrs. H.'s school, could not be done in a public school, unless the children had been previously trained in a Kindergarten.

Education at Home.

This report of what Mrs. Hopkins had accomplished pleased me, it came like good tidings from the future. I had seen one ten-year-old boy get what seemed to me "quite a clear vision of the course of leading events in our country during the last two hundred years," without any "memorizing" and with only one careful, though often interrupted, reading of the "Young Folks' History of the United States," read aloud by myself. I had seen the same child's delight at the age of five, in Mrs. Agassiz's "First Lesson in Natural History," and a year later, had seen how fast he gained a knowledge of physiology from my reading aloud a little at a time, that capital book, "History of a Mouthful of Bread." I had seen how he picked up for himself, without book or single teacher, the names of all the forest and ornamental trees he came across. Then I know, too, how the Swede and German children, among whom I have lived in the West, learn to speak two languages, quite correctly, when very young. More than all this, I have seen how almost all children are starved and stunted mentally, because we parents are too ignorant or too busy with other things to give them answers to their questions, and to surround them with conditions favorable to healthy mental growth.

Mental Strain.

But there is another side. I would not leave this subject of education here without an earnest word of warning against overtaxing the minds of children. Mental strain is like any other strain—of the back, or of the eyes, for instance. It may be slight, and excite little attention, or so severe as to get the name of "arrested development," or result in idiocy. I have known of children, who were wonders in their ability to learn and recite little verses, and in learning the alphabet, who suddenly came to a stand-still—hated all lessons, and afterwards learned with great difficulty. One little girl, who had been through an experience some like that, told me, when a dozen years old, that she didn't know why, but she could not put her mind fully upon anything. It would always wander in spite of her efforts to pay attention. Rest is the cure for a strain; rest for the mind when the mind is weary, and a long rest with a change to out-door amusement, when the mind has been seriously overtaxed.

Unbleached Window Shades.

Mary has been keeping house so short a time that she has no old "duds" to work over into cheap curtains. I don't know as she can do better than to take unbleached factory cloth. She can make drapery curtains of this if she likes, but if, like me, she wants to see out, and let the light in during the day, she will prefer shades. If her cloth is too wide for the window, she can make a broad hem each side. Then she may trim it with a narrow strip of some bright color—cheap worsted dress binding is most easily managed, though plain calico that will not fade may be used. The shades may be tied up by cords and tassels of the same color. If worsted dress-braid is used, the same will do for a cord, allowing enough in length for a generous bow when the shade is rolled up. Lambrequins of the same color in calico, flannel, or any material, of any pretty style, (the pattern books usually give them, or give an idea how one can make them without a pattern), give a pretty finish to the whole.

Rice and Tapioca Pudding.

In a pint of water, soak over night half a teacupful of rice and half a teacupful of tapioca. In the morning, add to this, cinnamon, or other flavoring; half, or three-fourths a teacupful of raisins; three-

fourths a cupful of sugar, and a quart of milk—a little more milk (or water) if you put in the raisins. Mix well, bake two hours, and eat cold.

This is a good pudding to make when eggs are scarce, or dear. I have found, too, that the milk used may be diluted nearly one-half, as milk grows scarce, by adding a teaspoonful of butter. But eggs are beginning to be plenty, as I write, and when this reaches my readers they will be at their cheapest and best. So here is a good recipe for

Tapioca Pudding with Eggs.

Soak one teacupful of tapioca in a pint of water for two hours or more. Add one quart of milk, and set it where it will heat gradually, without burning, stirring it occasionally until it seems quite soft. Set it where it will cool a little, while you beat well together the yolks of five eggs, one tablespoonful of butter, and half a teacupful of sugar. Stir this with the milk and tapioca, then add the beaten whites. Bake in a buttered dish. It is not necessary to soak tapioca before making into a pudding, if you heat it gradually in milk or water, stirring as it swells and softens—all this before you mix it with the other ingredients of the pudding.

Another Wood-Box.

In February last, we gave a rather elaborate design for a wood-box, and several others will be found in former volumes. In those places where wood is the fuel, it is found to be bulky, and to bring in that dread of the neat housekeeper—*dirt*. Hence some device for holding the wood, is necessary. We have, in former volumes, given neat wood-holders, for use in the sitting-room. We now give one for the kitchen, where the demand is constant, and should be supplied in the most convenient manner. Our correspondent, "H. T. S.," Wayne, N. Y., sends a device which will be useful where, as is often the case in country houses, the wood-house immediately joins the kitchen—a most convenient arrangement. His wood-box, as he says, "is only adapted to those dwellings where

WOOD BOX IN PARTITION.

the wood-house is next to the kitchen," as it should be where wood is the fuel. As shown by the engraving, the partition wall between the kitchen and wood-house is cut away, to allow the box to be supplied from the wood-house, and to deliver it where it is to be used—in the kitchen. As our correspondent says, "this will save many steps, and avoid much litter," two things every farmer's wife—indeed any other wife—will appreciate. The engraving sufficiently explains itself. The partition is shown with the parts of the box on each side, and the measurements of the box are given. The drawer at the lower part is for kindlings, and any of the stove appliances not in constant use.

A Strawberry Huller.

Where strawberries grow with a distinct neck, the operation of hulling is easy, and no aid is required to the fingers of the operator. But many varieties, especially those that produce very large berries, have the hull (or properly speaking, *calyx*), so closely attached to the fruit, that it is trouble-

some to remove it by the use of the finger and thumb, and when, as is often the case with the large berries, they grow in the "cockscomb" shape, the calyx is so malformed, and partly covered by the shoulders of the fruit, that it is impossible to remove it neatly without using a knife. We have seen two or three devices for hulling strawberries, but none so simple and practical, as that made by A. S. Buiker, of Lawrence, Mass. It consists of a pair of forceps, or tweezers, of the form shown in the engraving; they are apparently of brass, and silver-plated. Mr. B. sent us his huller too late

BUNKER'S STRAWBERRY HULLER.

last season for us to notice it then, and we now call attention to it well in advance of "strawberry time," at least in the Northern States, as an exceedingly useful little affair. As we preach for an abundance of fruit for others, we try to practice it for ourselves, and as in the season, strawberries are served usually three times a day, we had a fair chance to test the utility of this huller. Like most useful affairs, it is very simple, and its peculiar form allows it not only to save the fingers where the hulls present no especial difficulty, but with troublesome and cockscombed berries, it allows the calyx to be cut out neatly and quickly and leave the berry in a presentable condition.

Washing and Washing Machines.

Whatever may be the liquid used in washing, whether it be hot soap-suds, cold river water, with the "soap-root" of the Mexicans, or some of the various washing compounds, the mechanical operation is essentially the same. The Mexican woman souces your shirt in the river, lays it on a flat stone, and pounds it vigorously with another stone, regardless of buttons; others use a board and a stick; others put the clothes into a barrel and pound away at them with a heavy pounder. These primitive washing machines act upon the same principle, as do the more simple methods of rubbing the fabrics between the knuckles, or rubbing them upon a wash-board. In each and all of these, the pores of the fabric are filled with the water or suds, which is more or less violently squeezed out again, carrying with it the various soiling matters known by the comprehensive term *dirt*. We fill the clothes with all the water they will hold, and squeeze, rub, or pound it out again, and repeat this again and again, until the soiling matters are either dissolved out or are carried off mechanically by the liquid. The number of machines that have been contrived to perform this simple operation, and take the place of the knuckles, whether used against one another, or against the grooved washing-board, is beyond computation, some of them being ponderous and complicated, others almost as simple as the old pounding barrel, but in each the object is to fill the fabrics with suds and squeeze it out again, and those are most effective that most closely imitate the rubbing upon the wash-board. Hundreds of machines have been invented, but there is not one that may be said to have come into anything like general use. This is not from any fault in the machines themselves, for some of them are very effective, but from a strange perversity on the part of the very people whose labors they are intended to lighten—the working women, or "help." The average kitchen-maid, if she displays no tact or ingenuity in anything else, shows a wonderful ability in preventing a washing-machine from working, and the mistress, for the sake of peace and clean clothing, allows the servant to do the washing by "main strength and stupidity."

Hence it rarely happens that these machiues are used, except by those housekeepers who do their own work. A machine of any kind requires a certain amount of intelligence for its effective use, and this applies to washing-machines as well as steam-engines. The domestic labor-saving machine that, of all others, has been most generally accepted by the maid-servants, is the wringer; the utility of this was so manifest, and the contrast between turning a crank with ease, and wrenching the muscles of the arms and upper part of the body generally, in twisting the water out of a large sheet, so great, that in most cases prejudice gave way, and the wringer tolerated. Perhaps its resemblance to a wringer is one reason why the "Walker Washer" has so rapidly become popular, and has been used by those who could see no merit in machines of other styles. This washer, of which an engraving is given, is easily attached to any tub, whether square or round; a couple of sockets are screwed

THE WALKER WASHER.

to the sides of the tub, on the inside, and the machine can be put in place or taken out, in an instant, to allow the tub to be used for other purposes. The base of the washer is so arranged, by means of a sliding rod and set screw, that it will fit a tub of any size; this is shown in the engraving, a portion of the tub being cut away to allow the whole of the machine to be seen. The general construction of the washer is much like that of a wringer; the upper roller is of wood, and fluted; this is, by means of springs, pressed closely against the lower rolls, of which there are two, also of wood, and provided with broad rubber rings set about an inch apart. The clothes are soaped on the most soiled parts, and made up in convenient parcels; thus several small articles are laid inside of a larger one. The tub being furnished with *hot suds*, the clothes are passed between the large roller and the two smaller ones, back and forth, for a few minutes, the time being governed by the character of the articles. Here we have the principle already spoken of: the fabrics are filled with hot suds, this is firmly pressed out of them by the rollers, and they pass on the other side into suds again, and by the reverse motion this is again squeezed out, and so on alternately and rapidly, with the effect of removing the foreign matter, and little wear of the clothes. This being the structure and action of the washer, we have only to add that the writer has tried it for some time, and finds it to work in an eminently satisfactory manner. It is simple, easily worked, and moderate in price. This machine is manufactured by the Erie Washer Co., Erie, Pa., who give other particulars in our advertising columns.

Sensible Advice about Eggs, comes from a friend, "J.," Hartford, Conn., whose approach to the age of 80, shows that he has paid proper attention to his diet. He says: "I suppose it is generally admitted, that the best way to cook eggs, so far as health is concerned, is to boil them *soft*, say three minutes. If they are boiled three minutes, the white will be cooked *hard*, and the yolk will not be cooked at all. This way, therefore, does not allow us to cook eggs so as best to

promote health. Eggs should not be boiled at all; they should be "coddled" and perfectly soft when cooked.

How to Coddle Eggs.—Put the eggs into a vessel of water at a temperature of one hundred and seventy (170°) degrees Fab., and keep the water at that temperature from ten to fifteen minutes, when the eggs may be taken out, and the white will be a fine jelly, and the yolk will be cooked soft. The temperature should be tested by a thermometer, not *guessed at*. The quantity of water should be so large, that the introduction of the eggs will not materially reduce the temperature.

The Tin Pan Nuisance.

BY M. W. F., BRYN MAWR, NEAR PHILADELPHIA, PA.

"If I were Duke of this country," began Anaximander one evening, as we were enjoying our daily drive through a section of country of unusual elegance, "I would punish with banishment every man or woman who threw tin trumpery into the street."—"Ameu," said I, "and send them out of the country with a string of oyster cans for a necklace."—His remark was born of no new spectacle—we had seen the like a hundred times before—but in this instance it was especially aggravating. There was a large country-house on a noble eminence—a beautiful lawn extending in front to a fashionable avenue, and at one side to a public road, not fashionable, but greatly traveled, and in a small ravine that made a gap under the fence and opened into the roadside gutter, was tumbled a mélange of old tin-ware—coffee and tea-pots, pans, cups, watering pots, innumerable fruit and vegetable cans, and broken crockery. It was such an

ugly blotch on the otherwise fair beauty of the place, that one could not but wonder at the sight. What to do with such old trumpery, that cannot be burnt, seems to be an unsolved riddle with the majority of country people. In cities, the house-maid stuffs it in a barrel, which the ash and garbage-men carry away. In the country, it is commonly pitched into some out of the way place, under porch floors, into vacant cellars, under currant bushes, etc., but always where in some moment it is discovered, and is as unsightly to the eye of the lover of nature, as would be an eruption on a fair woman's face to a lover of the human race.

So far as my own experience goes, I know of no better way to dispose of broken and worn out wares, than to put them into a well dug for the purpose—one which has a cover, and which, when full, can be earthed and grassed over. Such a receptacle has its advantages—one always knows where to look for old basins and pans, if they are needed, for broken pottery when pieces are required for drainage, while bits of glass are thus put forever out of the way of the children's feet. If any body knows of a better way, let him make his method known in these columns, from philanthropic motives.

I must think, too, that the sight of old tin "lying around loose," has a charm for some people, judging from the way they distribute it in their backyards and front ditches. A man's back-yard is his private property, and if he chooses to make and to keep it a bideous looking place, it is an affair between himself and his conscience; but the man who makes a public highway the receptacle of his trumpery, should be prosecuted by the Commissioner of Roads, or some other apostle of public weal and public decency, and punished as a polluter of public morals. To be brought face to face with such unsightliness, is like an "evil communication" which corrupts good manners. There is a manifest indelicacy, as well, in allowing such broken and worn out domestic utensils to remain exposed to public view, and belongs to the same strain of untidiness and vulgarity that throws old shoes and crinoline in the street. So we advise, that every farm-house have its well or pit for unsalable and

unburnable trumpery, and thus bury so much of ugliness from the face of the earth.

BOYS & GIRLS' COLUMNS.

Aunt Sue's Chats.

AN INTERESTING GAME.—WORD MAKING.

S. F. BENNETT.—The most fascinating "game" that I have seen for a long time, is played with letters, and is called "word making;" or, if you prefer a more classical name, "Logomachy." Provide yourself with a box of letters. These may be had at the book and stationery stores, and contain several alphabets, each letter upon a separate small card. Any number of persons can play, but it is most enjoyable with three or four. To begin the game, let one person draw one letter from the box without looking at it; he places it right side up upon the table, in front of him; if it be A, O, or I, he can keep it as a *word*. The next person draws (say) Y, and not being able to make a word of it with the O (face up) by the first player, he places it in the pool on the center of the table. Number 3 draws (say) R, takes No. 1's O, and makes "OR." No. 4 draws E. He might then take the Y from the pool, and make "YE," but he prefers to take No. 3's "OR," and make "ORE." No. 1 draws again, (we are supposing that four persons are playing), and draws the letter B; he takes Y from the pool, and makes "BY." The words made, are placed in front of those making them, face up upon the table, and kept there until some one, by adding one or more letters, to form another word, takes one from its previous possessor. Who ever first gets ten words, wins the game, provided all the other players have played without being able to deprive him of one of the ten.

To make it plainer, let's use a diagram, and suppose that four persons are playing. Before them on the table are the words seen in the diagram. No. 4 draws the letter U, looks round the table to see what he can do with it, as it is generally preferable to take a word from some one of the other players, rather than to make a new word from the pool. He might make "BUD" by drawing from the pool, but he prefers to take No. 2's "HOG," and by adding to it the U, just drawn, and the C from the pool, he can make "COUGH;" then he takes the D from the pool, and adds it to his own "OFF," making "DOFF," and laughs at No. 3 for not having seen it. No. 1 then laughs at No. 4, the latter having finished, for not taking his "BE," adding the B from the pool, and making "EBB," which he proceeds to do himself before he uses the E that he has just drawn. With that he might make "FEZ" with the F and Z from the pool, but he prefers to take No. 2's "FROG" and make "FORGE" with it.

DIAGRAM OF WORD-MAKING GAME.

The foregoing illustration will show you that you can make a word at any time before drawing, if you happen to see a letter in the pool that you can weave into a word of your own, or some one else's. The right to use the letter drawn from the box, is not forfeited by forming a word from the pool. No *part* of a word can be taken from any player; the whole word must be taken, or none. You can not take one word from a player, and add it to a whole word of your own by merely adding a letter or two. For instance, if No. 1 has A, and No. 2 has I, No. 3 can not take the two, article and pronoun, by merely adding a D to them, ("AID"); if they were merely letters in the pool he could do so, or if No. 1 had A, and I were in the pool, then No. 3 could take the A for his "AID."

No word can be taken by simply changing it from a singular to a plural noun. If No. 1 had MITE, you could not make it MITES, and take it, but you could appropriate it by *transposing* it into "TIMES," or "ITEMS;" somebody's S could turn that again into SMITES. You may add an S when you turn a noun into a verb, *e. g.*—DANCE, DANCES; JUMP, JUMPS; CUFF, CUFFS; etc. You may add an S to pluralize one of your own nouns at any time. Proper names, geographical names, or foreign words, are not allowed. The dictionary must decide a question when the players are in doubt.

Before beginning the game, it is well to discuss the

rules and regulations with regard to plurals, obsolete words, etc., so that the players may be all of one mind. The game may be varied by making it sometimes entirely geographical or historical; another time it may be based upon authors or Bible names. In your anxiety to get your ten words, you will study your dictionary, and learn many a new word; and some of you will perhaps be surprised to find that there are such words as *morra*, *moresh*, *nider*, *nide*, *ait*, *brash*, *alb*, *abnet*, *toggle*, etc.

After the player has finished making all possible combinations, it saves time to draw the letter for his next turn, that he may be considering to what words he can add it. He can keep it hidden until his turn comes to play. It is well to put a watch upon the table, and decide before commencing the game that three minutes will be allowed to each person for consideration. If no word is taken from the party having ten words, before three minutes are up, the game is finished. If the player draws J, V, K, W, X, Z, or Q, or all of these letters, he has the privilege of drawing again, even though he has been able to add any of them to the others' words, or to letters in the pool. I should be pleased to get a postal card from any who try this game, and enjoy it.

"C. E. L."—The "Square" puzzle you send, was published in the *American Agriculturist* in October, 1877.

"J. K."—You will need four ounces of chinchilla worsted (single zephyr) for the "scarf," and three ounces of scarlet. One ounce of the latter is for the fringe. Set up 30 stitches on small wooden knitting needles. The "sontag-stitch" is a very pretty one for the purpose. The advantage of this stitch is, that there is no "right or wrong" side. In case you are not familiar with the stitch, I can make you acquainted with it in a very few words: "Slip one, thread over, knit two together." Knit ten rows of chinchilla, then half an ounce of scarlet, then ten more of chinchilla, and half an ounce of scarlet, (being careful to join your thread at the commencement of a row, never in the middle). Now knit the remainder of your chinchilla worsted, all but enough for the twenty rows beyond the scarlet stripes at the other end. Tie in your fringe. *Ribbed* scarfs are also pretty, ("two plain and two purled").

E. B. M. D. asks for "directions how to piece 'Log-cabin' quilts, and also how to net ties, etc. I wish to net a bed-spread with white cotton."—I would not undertake to tell you *how* to net, for I know I should "get all tied up in a hard-knot" myself, if I should attempt it. I would recommend you to get a book which gives "instruction in knitting, netting, and crochet work." I can, however, help you to the "Log-cabin" pattern, one block of which is shown in the figure. Begin with a piece of silk, one

inch square, for the center piece; then provide four pieces 1 by 2 inches, four pieces 1 by 3, four pieces 1 by 4, and four pieces more 1 by 5 inches. Let half of them be of dark, and half of light silk, and arrange them as seen in the pattern. When your blocks are all completed, you can join them together—being careful to keep the dark shades all running the same way—or you can separate them by strips, three or four inches wide, of black silk. It adds very much to the effectiveness, to make the center square (of each block) of black velvet.

Our Young Microscopists' Club.

I invited you, and you have come. Such a lot! Well, I am glad to have you tell me what you are doing, but you must not expect me to notice you all in these talks. I can only find space to notice those who wish their questions answered, and who tell something of use to the rest. One Minnesota boy, to whom a relative gave a \$50 Microscope, wishes one of our instruments in order that he may belong to our "Club."... I was reading the other day, in a large work, about the Microscope, and came across something that I thought would interest you. The author stated that many of the figures given of the minute objects seen by the costly and powerful Microscopes, were not true, that they were due to what is called

OPTICAL ILLUSION;

that is, the impression upon the mind is a false one, and we do not always see things as they really are. He illustrated this by a series of round black spots, placed equally distant from one another and separated by a white space, as in figure 1. If you hold this about 18 inches from the eye, although you know the spots to be circles, if you look at them steadily, they will appear to be hexagons, or six-sided spots. I introduce

Fig. 1. DECEPTIVE SPOTS.

can not always trust our eyes, but must look at all the things that we examine with the Microscope, very carefully and in various ways, looking at them as both opaque and as transparent objects. Several have, from time to time, asked me about a swift moving, silvery looking little creature, now and then found in drawers, and among books that have not been disturbed for some time. Some call it

"THE SILVER-FISH,"

as it has a fish-like shape and a silvery color; in England it is known as the "Sugar-Louse." It is about one-third of an inch long, and of the shape shown in figure 2. It is really an insect, and belongs in that class of insects that have no wings, with the lice, ticks, mites, and others. Its scientific name is *Lepisma saccharina*. Its first or

Fig. 2.—LEPISMA, OR "SUGAR-LOUSE."

generic name, *Lepisma*, is from a Greek word, meaning "to scale off," probably because its scales come off so easily, and its second, or specific name, *saccharina*, refers to its fondness for sugar. It is said to be very fond of sweetmeats of all kinds, and is charged with eating silks, and with injuring books, though some say that it is only found among books, because it is after the mites which do the mischief. However, I have never seen them numerous enough to do much injury. When you catch one, you will find that, by a touch, this silvery dust with which it is covered, will come off upon your finger; transfer some of this to a glass slide and examine it, you will find that each minute particle of that which seems like dust

IS A BEAUTIFUL SCALE,

and presents the appearance of figure 3. Though a small object for your Microscope, you can make out the form of the scales; some are long and fan-shaped, and others circular. You may be able to see the lengthwise lines if you are careful. This is one of the objects used to test the powerful Microscopes; an instrument of sufficient power will show not only the lengthwise lines, but cross markings. The scales on the

Fig. 3. SCALE.

WINGS OF BUTTERFLIES AND MOTHS

are much larger than these, and you will find them very interesting objects. Something is said about these on the circular that goes with the Microscope, and now that these insects will soon be about, you must be on the look out for them. Not only the scales of insects, but

THE SCALES OF SMALL FISHES.

will be found worth looking at as opaque and transparent objects. That you may see what pretty objects the scales are, I procured a few from such common fishes as happened to be in the market, that you may see how they look when magnified with our Microscope. Figure 4 is from the Smelt, a pretty little fish not found a great ways from salt water. When magnified, each scale looks like a beautiful shield with its surface wrought in delicate lines. A much more common fish is the Pickerel, which, in the course of the season, most of you will be likely to come across. Its scale is shown in figure 5. The notched

Fig. 4.—SMELT.

Fig. 5.—PICKEREL.

edge is where it is attached to the skin. Still more common is the Yellow Perch, found in almost every fresh water stream or pond in the country, and though so common, its scale (fig. 6) is one of the most interesting. Here you have some very distinct teeth or notches, and the opposite edge, the exposed part—or as carpenters say about shingles, the part "to the weather,"—appears quite different from the other; it is finely marked with lines, and at the very edge you will be able to see a very minute little fringe of points. These will serve as examples, but you will come across a great many other fishes, and no matter if they are said to have no scales—for many fishes pass for scaleless, because the scales are very small and hidden by the skin—examine the skin with your glass. When you come across an interesting scale, it is well to preserve a little lot, to have some to exchange with your friends. Scrape them off gently with

a knife, and place them in a saucer, or other small dish of water. Stir them about gently with the finger, and when they settle, pour off the water; repeat the washing several times, or until they seem to be free from all slime; then place them on a paper—newspaper is better than glazed writing paper—fold it over, and put it under a hook, or other weight, to dry. When dry, you can put them up in a fold of nice paper, and label them. In examining the scales you will often find a number stuck together, in which case you must pick them apart with your needles. You must look at them both as opaque and as transparent objects, and by carefully managing the light, you may find that it is not well to have too strong a light to see them best.

Fig. 6.—PERCH.

AS TO MOUNTING SCALES.

I am not quite ready to tell you about this, for I wish to try some experiments, to hit upon the way that will be easiest and the cheapest for you. They will keep perfectly well until you are ready to mount them.

In the pools of water found almost everywhere, especially in spring, even if they dry up later in the summer months, you will, if not this month, next month or later, find on the surface an abundance of

GREEN SCUM, OR "BROOK-SILK,"

as it is often called. If you take up a bit of it, you will find it is made up of fine threads, as fine as, or finer than, the fibres of silk. You will often find this of interest to examine with your Microscope. These threads are really plants, and belong to the great family of *Alga*, of which the seaweeds form so large a part. These *Alga* are flowerless plants, that is, have no regular flowers and seeds, as do the plants we are most familiar with, and they are often very simple, consisting of just a minute little cell, or sac—just a microscopic bag—without root, stem, or leaves, and yet be a complete plant, which is multiplied by breaking up into other little bags like itself. But our Brook-silk is not so simple as this; it consists of longish cells or bags, placed end to end, as in figure 7. There are many kinds to be found in our waters, and you may not all find what I am about to describe.

7. BROOK-SILK. 8.

The threads of some of the Brook-silks, when magnified, appear as in figure 7, transparent long cells, with green matter inside, and this is often arranged in spiral regular coils. The whole mass as it floats on the water is like

A BRIGHT GREEN SCUM.

Later in the season, you will find this scum looking dull, and much of its green color faded. Examine it from time to time, and you may be fortunate enough to catch it at the right time to see its curious manner of multiplying. Several of these plants behave in the manner shown in figure 8. In two threads laying side by side, the cells (or joints,) will bulge out towards one another; at length the projecting parts of the cells will meet, and grow together, the division between them will break away, and all the green matter in one, will run over into the other; the contents of the two cells thus joined will form an oval green mass, seen in the upper part of figure 8, which is called a *spore*, and answers to these plants the same purpose as seeds do to common plants. When the cell breaks up to allow this to escape, it will probably fall to the bottom and wait there until next spring to continue the growth. I do not expect that all of you will succeed in seeing this, but it is worth while to try.... Among the things to be looked for in the spring water pools is the

"REVOLVING GLOBE."—*Volvox Globator*.

I do not know how plenty it is every where, but when I lived in one of the Western States, I could hardly go amiss for it. Where there was a water-hole, a pint of water dipped up from it, would be very sure to contain several of these curious globes. It is just large enough to be seen by the naked eye, and if you get a jar of water from such pools, and can see a very tiny globe swimming around in it, you may be pretty sure that you have the *volvox*. But if your jar holds a quart, how are you to catch it? The microscopists have a very neat trick with

THE "DIPPING TUBE."

This is a glass tube of six inches or more in length, and about the diameter of a common lead pencil. Druggists generally keep glass tubes of various sizes, and will supply one for a small price. A tube of this kind is fre-

quently required to catch small objects that we wish to examine. Suppose we have a jar of water in which the *volvox* is seen traveling about. You take the tube in hand, with the forefinger pressed over its upper end, as shown in figure 9. So long as the upper end of the tube is kept closed, no water can enter the lower end. Now if you direct the lower end of the tube, keeping the finger closely pressed over the upper end, towards the *volvox* or other object which you wish to catch, even if no nearer to it than half an inch or more, and suddenly remove the finger from the upper end of the tube, the water will at once rush in to the tube, and carry with it the *volvox*. Now put the finger again over the upper end of the tube, and lift that from the water. It will hold the water, and whatever you have caught. Having your *volvox* in the tube, you wish to get it into the cell of your microscope. Here no description will help you, you must exercise

Fig. 9.—DIPPING TUBE.

tact. You have perfect control over the water in the tube; by letting the air in from above, by the slightest raising of the finger, the water will flow out at the lower end. I could show you in a minute how to get the *volvox* from the tube to the cell, though I can't readily describe it, but if you have any *gumption*, you will, if not at the first trial, succeed at the second attempt. Having the

REVOLVING GLOBE, OR VOLVOX,

in the cell, you will examine it, and a puzzling thing you will find it. A globular, greenish body that moves about, going around and around, in a most knowing manner; and you will say: "What a curious little animal." But it is not an animal at all; it is really a plant, or rather a collection of plants. You know that the plants you are most familiar with, are fast rooted in the ground, and do not move at all. But there are some water-plants that act so much like animals in their movements that they were for a long time considered as animals. The *volvox* is only one of these strange plants that move about in the water. As you look at it under the Microscope, having placed it in the cell, with a few drops of water, it will appear as in figure 10, a globe with green spots all over it, and it may be you can see the hairs on the surface, which, by their movements, make it sail about. I can now only tell you about this strange object, that it is

Fig. 10.—VOLVOX.

a colony of distinct individuals collected in a globe form. Each individual plant is a little green bag, with two hairs, as in figure 11, and many of these unite to make the globe, all with their hairs outward, and as these hairs are capable of rapid motion, they roll the whole along very curiously. Before I can tell you more about the *volvox*, I must examine some myself, to see how far our Microscope will show its history. As it is large enough to be seen by the naked eye, I know that it will be worth looking for, and that its movements, should you catch it, will afford you much amusement. I wish to suggest, as a great help to the Microscope,

A LITTLE AQUARIUM,

which may be any glass vessel, a common fruit jar, answering as well as anything. Into this you can put various water-plants, with water from a pool or pond, and you will find numerous things in the jar that you can catch with your dipping tubes to examine with the Microscope. Later in the season, when the *Duck weeds* appear on the surface of quiet waters, you must put a lot of them into your jar. These are curious little plants, shaped like flux-seed, but larger, that float upon the surface, with their roots hanging down in the water. The roots of these are the favorite resort of many curious microscopic animals, and will afford you a harvest of curious things. In the mean time put some clean gravel, an inch or so, in the bottom of your jar, and then put into it any delicate water-plants you come across. If they were rooted where you found them, tie a small stone to their roots and place them in the jar. Put in some snails, that you may watch their eggs, as mentioned last month,

FOR THIS MONTH,

besides what special things have been mentioned, you will need to look after the eggs of insects of various kinds, some of which are objects of great beauty. Insects, as a general thing, place their eggs, for safety, on the underside of a leaf, though some do not observe this precaution. Small flowers will now be abundant, and you will find that even the smallest, is an object of beauty when magnified. Leaves will now be plenty, and it will be well to examine all those that are rough or downy, as you will often find that the scales which give the roughness, and the hairs that make them downy, are beautiful objects under the Microscope. Of course I can not suggest every use you will find for the Microscope, and I have only tried to point out the most easily found, curious things, with a view to showing you how much is hidden from ordinary sight, and also to get you in the way of examining every thing that you meet in your daily walks and work. THE DOCTOR.

An Easily Made Eel-Pot.

Some time ago we told of some of the methods of catching eels; now "G. L." of Machias, Me., sends a description of an Eel-pot, as a trap for eels is called, which any boy can construct, and which will no doubt answer as well as any. A common flour harrel has many half inch holes bored all over it, and a piece about 8 in. square cut from one side for a door; the pieces cut out will make the cover, which may be put on with a leather hinge and a button to hold it fast. In one head (or both

AN EEL-POT MADE FROM A BARREL.

if you choose) put a spout, flush or even with the head on the outside, and projecting into the harrel about 10 inches. Upon the end of this, within the barrel, draw a leg of an old stocking, or a piece of one, to hang down over the end of the spout. Stones enough to sink it, are put into the barrel. Fasten a line to the trap, to the other end of which tie a stick of wood for a buoy, so that you can find it, and having put in the bait and made the cover fast, you are ready to sink it where eels are to be found. The engraving shows the arrangement; *a* is the door, *b* the spout, the dotted lines showing the part within the trap, with the stocking leg (*c*) over the end. This stocking leg is the ingenious part of the whole affair. An eel, attracted by the bait, will make its way into the spout and push through the stocking leg, which, as soon as it has passed through, will drop down and act like a valve to cover the entrance, and when once fairly in the trap, we don't think that the slipperiest of these most slippery fishes could ever find the way out. One correspondent charges us with publishing

"AN INJURIOUS SCANDAL"

about his favorite fish. We said of the bait to put into the pot, "no matter if somewhat old," as we had long ago learned from experienced fishermen. This gentleman (a correspondent of "Aunt Sue," who sends us the letter, (done with a "machine,")) says that the eel is very particular about its food, and if one wishes to catch him, he must use only "bait of the freshest and sweetest."

Aunt Sue's Puzzle-Box.

ALPHABETICAL QUERIES.

1. What letter, inverted, names a vegetable?
2. What two letters, right side up, name two other vegetables?
3. What letter names an insect?
4. What letter names a pronoun?
5. What three letters name three verbs?
6. What letter names a bird?
7. What letter names "the window of the soul"?
8. What letter gives an order to an animal?
9. What letter names a river?
10. What letter asks a question?
11. What letter is twice yourself?
12. What letter gives a hint?
13. What colored letter gives a geographical name?
14. What speckled letter can anticipate?
15. What foreign letter names a title?
16. What letter, with a piece of wood over it, names another title?
17. What letter names a measure?

JOHNNIE.

CHARADE.

"Breakers ahead"; the sailor cries,
From the tap'ring mast's high head.
"Bout ship," the watchful pilot's shout,
"On my first there's naught to dread."

My second both as first and last,
Enfolds most every land,
Whilst not a single bounding sea
But's limited by its hand.

My third, how welcome in the spring,
Companion of the tender lamb.
I'm one possession of the poor,
Which wealth may not command.

O'er my whole the youthful mother toils,
Her expectant babe t'adorn,
Again with care elaborates,
Her widow's grief to mourn.

Anon the lawyer me demands,
His brief and argument t'arrange,
Then I puzzle clerks and all
With figures curious and strange.

The printer too with fingers deft
Selects me from his case,
And in great form I'm daily spread,
T'enlighten every race.

With joyous youth I haste to school,
Till comes the glad vacation,
When high in air, I take my flight,
Sure sign of exultation.

J. A. B.

NUMERICAL ENIGMA.

I am composed of 77 letters:

- My 1, 61, 7, 35, 45, is a weapon.
- My 8, 21, 40, 72, 55, is a vegetable useful for its shell.
- My 10, 3, 52, 41, 69, is an animal whose fur is valuable.
- My 12, 24, 8, 36, 64, is a musical instrument.
- My 14, 2, 56, 46, 30, is a part of the body.
- My 16, 5, 25, 42, 51, is a bird.
- My 23, 33, 15, 63, 42, is a domestic animal.
- My 68, 53, 37, 16, 2, is ditto.
- My 47, 20, 8, 34, 4, is a wild animal.
- My 42, 1, 18, 73, 31, is the name of one of the gods.
- My 26, 76, 42, 6, 19, is ditto.
- My 58, 9, 56, 7, 61, is the name of a goddess.
- My 70, 15, 23, 49, 3, was the goddess of the family.
- My 77, 41, 66, 67, 59, is a very lazy animal.
- My 29, 44, 71, 39, 11, is a small bird with long wings.
- My 37, 3, 62, 28, 57, is a black bird.
- My 50, 38, 24, 43, 5, is a bird remarkable for its directly ascending flight.
- My 32, 4, 75, 22, 13, is a fish.
- My 44, 27, 60, 36, 17, is a grain.
- My 54, 48, 65, 74, 10, is an aquatic flowering plant.
- My whole is a proverb.

ISOLA.

CROSS-WORD.

My first is in canter but not in walk,
My next is in scolding but not in talk,
My third is in cavern but not in dell,
My fourth is in Sarah but not in Belle,
My fifth is in minute but not in hour,
My sixth is in oatmeal but not in flour,
My seventh is in ginger but not in mace,
My eighth is in contest but not in race,
My ninth is in spider but not in fly,
My tenth is in rainy but not in dry,
My eleventh is in sear but not in wash,
My twelfth is in pumpkin but not in squash,
My thirteenth is in purple but not in white,
My fourteenth is in darkness but not in night:
My whole is a city of some renown
On the map of Europe 'tis written down. C. E. A.

A Spring Day in the Country.

We have before told you about our pictures. Some of them we give because they teach something, whether about our own, or some other country; other pictures are given merely because they amuse; others still, simply because they are *pictures*, and these, without any thought of what they may teach, are given because they are pleasant to look upon, as specimens of the engraver's art. If, in addition to this, they tell any story, all the better. If you were to compare the above picture with that of some costly city building in this country, or with that of some celebrated structure in the old world, or of some renowned ruin, we think that *our* youngsters would prefer this picture. If we were to ask you why? you would say: "It is home-like. I have seen something very much like that somewhere; I am sure that I have seen just such trees, standing by the side of a run or stream. There are boys engaged in fishing, too. I have fished in just such a stream, where there were trees like these, but"—We know why you say "but," for there is the old building, part house and part mill, with its "flume" to carry the water to the wheel. Then the style of the building is quite unlike anything that has been built within the last hundred years, so you reluctantly give it up, and admit that it is a place you never saw. "But is there any such place?" some will ask. Yes, it is a scene in Maryland, which you know is one of the oldest States, and probably the building, for there are many such, was put up long before the war of Independence. We chose it because it was so good a specimen of wood-engraving, and withal so pleasing a picture. The trees look like trees, and the water like water, while the building and all its surroundings, tell as plainly as need be, of days long gone by. So we give the picture because it is a good and pleasing one. But as you look at it, does it suggest nothing to you? The stream runs quietly, the trees are in leaf, the boys enjoy themselves at fishing, and a general air of quiet over the whole, suggests a pleasing "Spring Day in the Country." Ah, these spring days! now present to some of you, and soon to come to others, are there any other days like them? When are the leaves so fresh in their greenery, when

do we find such wild flowers, when do the birds sing so joyously, when does the stream ripple so laughingly as in those spring days, when the very air is filled with light and life and loveliness? Many a rich old man, were he to study this picture, would forget that he had, these many years, trodden the hard pavement, while the only glimpse of nature he could get, was by looking up between the walls of brick and stone, to the strip of blue sky, the same sky of which as a boy, he saw the whole canopy. You boys, who look upon this picture of a "Spring Day in the Country," try to see your present blessings, the pure air, the open country, the grand old trees, the swift-running stream, the singing birds, the humming insect's, while above all is the glorious sky, and all filled with the abundant sunlight. These are all grand and good, but these overhang and surround a place called *home*. There are a mother, a father, and brothers and sisters, whose love makes it always a "Spring Day in the Country." Are you—as many boys are—discontented? Do you wish to seek another life in the city, or elsewhere, away from home? Take one of these lovely spring days now here, or at hand, and go off by yourself, and think over the matter. Put all that you now have and can enjoy, on the one side, and all that you hope to have, after years of toil—in which you have lost all delight in country pleasures on the other—and then ask yourself "Is it worth while?" Mind, we do not say that no boys should leave the farm for a city life, but we do say that many make the change without proper thought. In these days the "spring-fever" is on; that feeling of discontent, when neither body or mind are at ease. Every boy 15 years old has probably had the "spring-fever," and at those times is very unhappy. When this comes, get your fishing rod and lines, and go to some quiet stream and fish and think. We do not expect you will catch any fish, but something better. Look around at the fresh forest, look down at the starting grass, look up at the sky overhead, and see if this world, especially your part of it, is so bad as it seems. If you don't take home any fish, you will have had a plenty of fishing, which should bring a more contented spirit, and your Spring Day in the Country will not have been wasted.

TEAS

This is a combination of capitalists to supply consumers only throughout the United States with **PURE TEAS** at prices never before known, on the mutual principle, by getting up clubs. Send for New Price-List.

Fine Hardy Perennial Flowers.

To enjoy flowers with the least trouble, procure and plant those which, when

ONCE PLANTED, WILL BLOOM FOR YEARS.

No trouble with seed-sowing—with hot-beds, or green-houses. The plants will soon form clumps large enough to divide. They are

EVERYBODY'S FLOWERS.

We have by far the largest collection of these plants in the country, including everything from the old-fashioned Bee Balm and Moss Pink, to the latest introductions from all parts of the world. Our Catalogue for 1878, containing the latest additions, and giving much useful information about these popular plants, sent by mail.

WOOLSON & CO., Passaic, N. J.

"ONLY THE BEST."

The New York Weekly Witness says: The New England Silver Plate Co., of New Haven, Ct., are reliable, and make a very attractive offer.

The Illustrated Christian Weekly, published by the American Tract Society, New York, says: The New England Silver Plate Co., of New Haven, Ct., are no humbugs, but will do just as they represent.

The New York Weekly Sun says: The New England Silver Plate Co., of New Haven, furnish first-class articles at a very low price.

Do not confound these first-class goods with the ordinary cheap qualities. They are guaranteed to be exactly as represented, or the money will be refunded.

Silver Plated Table Bells, 80 cts. Napkin Rings from 40 cts. to \$1.75 each.

H. W. JOHNS' ASBESTOS Liquid Paints.

These Paints are in every respect strictly first class, and second to no others in the market in purity, richness, and permanency of color, beauty of finish, and durability. They are prepared ready for the brush, in sixteen newest shades, and standard colors, suitable for the tasteful decoration of all classes of buildings, inside and out, and for all purposes where a perfect protective coating is required.

They contain no water, alkali, or other useless or deleterious ingredients, such as are used in nearly all the ready mixed or so-called chemical paints, and are guaranteed to be the most durable paints in the world for exposed wood and iron work.

Owing to the wonderful covering properties of these Paints, the farmer, merchant, and manufacturer can, by their use, preserve and beautify their buildings, fences, or other wood and iron work, at from one-half to two-thirds of the usual cost of other ready mixed paints, or white lead and linseed oil. These Paints are sold by standard U. S. gallon measure, and our packages contain from EIGHT to TWELVE PER CENT MORE PAINT than those usually sold.

ASBESTOS ROOF PAINT, for tin and shingle roofs, iron-work, agricultural implements, fences, out-buildings, etc. We guarantee this to be a better article than has ever before been offered to the public for similar purposes.

TRY THE ORANGE COUNTY SEEDS.—
See Advertisement on Page 151.

MRS. OLD FOGY DOES NOT USE THE ROBBINS WASHER.

MRS. COMMON SENSE DOES. TAKE YOUR CHOICE.

TO MAKE MONEY SECURE AN AGENCY

FOR THE

CELEBRATED

ROBBINS FAMILY WASHER.

This machine has been ON TRIAL for the past six months in every State and Territory in the Union, and the almost unanimous verdict of housekeepers is this: "**Your Washer has proved a complete success.**" Some of the reasons why this popular verdict has been reached may be found in these facts:

The Robbins Washer is an entirely NEW MACHINE. It is constructed upon a NEW PRINCIPLE—that of forcing water by downward pressure through the fabric. The dirt or discoloration is removed by water force—there is no rubbing or friction about it. This principle is the only one that has ever been successfully applied to the cleaning of fabrics by machinery. All others have failed in one or more essential points. The Robbins Washer will cleanse perfectly, without rubbing, all kinds of wearing apparel, table or bed linen. It will not injure the most delicate fabric. It is the greatest bleacher extant, and for this purpose alone is worth ten times the price of the machine. It is simple, self-operating, never gets out of order, and will last a lifetime. It saves time; it saves labor; it saves material.

By purchasing a **ROBBINS WASHER** you can count the hard drudgery of the washboard among the things of the past.

Therefore, we confidently say to every housekeeper in the land, You want a **ROBBINS WASHER**. You cannot afford to be without one. It will pay to buy one.

THE RETAIL PRICE IS ONLY \$3.50.

Sample to those desiring agencies, \$3.

In bringing the Robbins Washer before the public it becomes necessary to take into brief consideration the

ART OF CLEANSING FABRICS,

which, although so common, is yet imperfectly understood. Having had a lifelong experience in the laundry business—in care, in water works, hotels, public laundries, asylums, hospitals, &c.—we know whereof we speak. The numerous devices of friction rollers, pounders, squeezers, dashers, agitators, steam wash boilers, &c., have all done very well, so far as it was possible for such principles and devices to do. But they have all failed in one or more of the three essential points, viz.: The saving of labor, the wear and tear of clothes, or in perfectly extracting the dirt or discoloration of which are accomplished by the **ROBBINS LITTLE WASHER**.

WHAT IS IT THAT REMOVES THE DIRT?

You may ask all washerwomen and housekeepers, and your answer from nine out of ten will be: "Plenty of elbow grease, or, in other words, plenty of hard, laborious rubbing on the washboard. And such is the case, for you first have to rub soap upon the cloth, then you have to rub it in to make the dirt soluble. But does that remove it? No; to do that you must first dip it in the water, and then rub it in again to force water through the fabric. That is what removes dirt after being softened by the chemical action of the soap upon it.

The way in which this could be the most economically accomplished is what we have so long and patiently sought after, and at last a principle has been demonstrated that in uniting all the above named, in

THE PRINCIPLE OF THE LITTLE WASHER

is embodied all the essential points. First, we have the desired heat, which expands the fabric and causes it to discharge the dirt. Second, we obtain a powerful suction beneath the clothes, which causes a rapid downward current of water force through and through them, thereby removing the dirt. Third, we use a large body of water, which holds the dirt in solution. Thus we cleanse thoroughly, rinsing the clothes as usual being all that is required to complete the operation.

The Washer is composed of solid galvanized iron, which will not rust or corrode. There are two sizes—the No. 1, or family size, for ordinary household use; and No. 2, or hotel size, suitable for country hotels, boarding-houses, laundries, &c.

OUR METHOD OF HANDLING.

We want agents everywhere throughout the United States, in every State, county, town, and hamlet. The retail price of No. 1 Washer is \$3.50; of No. 2 Washer, \$5. But we sell sample machines of No. 1 size at \$3; No. 2, or small hotel size, at \$4. Canvassers for this Washer can make more money with them with anything ever before offered to the public. As, for instance, we established two agencies to test the sale of the Washer upon its merits—one in Naugatuck, Conn., and one in Providence, R. I. The former, Mr. Charles Daniels, in a town of about 2,000 inhabitants, sold by canvassing in two weeks eighty-two Washers. In the latter place Mr. James Roberts, now of Naugatuck, Conn., sold in less than three months, without canvassing or advertising outside the store, over 500 Washers. A thing never before heard of.

TO PERSONS OUT OF EMPLOYMENT

we would say, if you want to secure a paying business, now is your time. Don't wait till the best territory is taken up, but send at once for sample machine and go to work. By following instructions you can sell to nearly every family in your neighborhood. Others have done it, and there is no reason why you should not. Full directions and instructions accompany each machine. Also, special terms to agents, circulars, testimonials, &c.

All orders must be accompanied with cash.

Remit by money order or registered letter to

THE GEO. D. BISSELL COMPANY,
Naugatuck, Conn.

SOLID SILVER TEA SPOONS, AT MANUFACTURER'S COST PRICES,

is what we can supply the readers of this paper, if desired, at a price as low as any jeweler pays for them at wholesale. We will mail on receipt of price, one set of six **SOLID Silver Tea Spoons** for \$3.50. (cost at retail from \$6 to \$7), or, for 85 cents, which covers the cost of the spoons, as well as postage and packing.

ONE SET OF 6 QUADRUPLE TEA SPOONS IN CASE, finely and heavily plated with **PURE NICKEL and COIN SILVER**, on a new metal, called **Alfenide**, which is very similar to the finest English white steel. It contains no brass or German silver in its composition, and consequently no poison, or disagreeable taste. Are very strong and will wear for years. Two sets, \$1.50. We shall not furnish these goods to the trade, consequently they cannot be supplied by any other manufacturer or dealer. We also make of same quality, Table Spoons 6 for \$1.75; Forks, 6 for \$1.75; Table Knives, balanced, solid steel handle and blade, triple plate, 6 for \$2. **New England Silver Plate Co., Man'rs New Haven, Ct.**

Copyrighted, New England Silver Plate Co., 1877.

BLISS' SELECT GARDEN SEEDS.

New Varieties Potatoes.

BLISS' TRIUMPH.—A new and early variety. Ten days earlier than the Early Rose; one of the most promising varieties we have ever offered.

TROPHY.—This fine, second early variety resembles the Snowflake in shape and quality. It has a beautiful red skin, and may be justly called a "Red Skin Snowflake."

Price of each variety, \$1.00 per lb., 3 lbs., \$2.50, by mail post-paid.

MANHATTAN.—A new round late variety, with purple skin occasionally blotched with white, very hardy, of vigorous growth, flesh very solid, white, and of fine quality. It is enormously productive, an excellent keeper, and a most desirable variety for the main crop.

Price, 75 cts. per lb.; 3 lbs., \$2.00; by mail, post-paid.

HARLEQUIN, or VARIEGATED-LEAVED EARLY ROSE.—A sport of the Early Rose, with beautifully variegated foliage.

Price, \$1.00 per lb. Single tubers, 25 cts.

ALPHA.—The earliest variety known, and of extra fine quality—matures its crop in 35 days.

BLISS' IMPROVED PEACHBLOW.—A cross between the well-known Jersey Peach Blow and the Excelsior, resembling the Peach Blow in appearance. In quality and earliness it far exceeds that variety, and will produce double the quantity.

ALPHA AND IMPROVED PEACHBLOW will be mailed, post-paid, per lb., 60 cts.; 3 lbs., to one address, \$1.25. Peck, \$1.00; bush, \$3.00; bbl., \$7.00.

SNOWFLAKE, RUBY, SUPERIOR, CENTENNIAL, and all other popular varieties, at the lowest market prices. 60 cts. per lb.; 3 lbs., \$1.25. For prices by bbl., see Potato Catalogue.

The Great Centennial Exhibit.

500 Named Varieties Potatoes.

The largest collection in the world, for which was awarded the Grand Centennial Prize Medal and Diploma.

One tuber each of the entire collection, correctly labeled, and carefully packed, express or postage prepaid: 500 varieties, \$100; 250 varieties, \$50; 100 varieties, \$25; 50 varieties, \$15; 25 varieties, \$8.

Bliss' Illustrated Potato Catalogue contains a list of 500 varieties, beautifully illustrated; also much useful information upon the cultivation of this valuable esculent. **10 Cents.**

Two New Varieties of Sweet Corn.

DOLLY DUTTON.—The earliest Sweet Corn ever introduced. A very dwarf growing sort, stalks from three to four feet high. Ears small, averaging from four to five inches in length, kernels of good size, tender, very sweet and delicious. It ripens from seven to ten days earlier than the early Minnesota, and is of much better quality.

Package containing sufficient for fifty hills, 25 cents; five packages for \$1.00; selected ears 15 cents each; two for 25 cents; \$.25 per dozen.

WASHINGTON MARKET.—This is, without exception, the best of the large varieties of Sweet Corn, and when better known, will, we are confident, become a standard variety for general cultivation. Stalks strong and vigorous, averaging about seven feet in height. Ears large, having from twelve to fifteen rows of kernels of good size, and very productive. It is very sweet and tender, and of delicious flavor, surpassing all others. It will be found one of the most profitable varieties for the market, and, on account of its superiority, will bring a much higher price than the ordinary varieties. For canning purposes, it has no equal. Packets containing sufficient seed for 100 hills, 25 cents; 50 cents per pint; 75 cents per quart.

Bliss' Illustrated Seed Catalogue and Amateur's Guide to the Flower and Kitchen Garden. One of the most valuable works on gardening ever published. 222 pages, 600 illustrations, price **35 Cents.**

Bliss' Illustrated Gardeners' Almanac for 1878, and Abridged Catalogue. 136 pages, with Monthly Calendar of Operations, with many valuable illustrations, **10 Cents.**

Bliss' Illustrated Handbook, for the Farm and the Garden, and abridged Catalogue of Garden, Field, and Flower Seeds, Fertilizers, Agricultural Implements, etc., etc. One hundred pages, many illustrations. Three cents.

Bliss' Illustrated Catalogue of Plants, for the Greenhouse, Conservatory, Lawn, and Flower Garden, and Bliss' Illustrated List of Novelties for 1878, mailed free to all. Address,

\$250 in Premiums.

Pringle's New Hybrid Spring Wheats.

CHAMPLAIN.—A bearded variety—a cross between the Black Sea and Golden Drop—combining the remarkable hardness of the former, with the superior quality of the latter. Its strong and vigorous straw, growing 6 to 12 inches higher than its parent varieties, stands erect, frequently bearing even in very ordinary culture heads from 5 to 6 inches in length, containing from 60 to 75 kernels each.

Price, \$1.00 per lb.; 3 lbs. \$2.50, by mail, post-paid.

DEFIANCE.—Another variety of Spring Wheat of the highest promise, the result of a series of experiments, to incorporate superior qualities upon the hardy stock of our common Club Wheat, by hybridizing it with one of the finest, whitest, and most extensively grown sorts of the Pacific Coast.

This variety displays great productiveness, vigor, and hardness. It is a beardless, white chaff wheat, with heads frequently 5 to 6 inches long, very closely set with large white kernels, frequently numbering 75 to 80 to the single head.

Price, \$1 per lb.; 3 lbs. \$2.50, by mail, post-paid.

In order to induce Wheat Growers to give these new sorts a thorough and universal trial, we offer **\$250 in premiums** for the largest quantities grown from 1 pound of seed, also for the 20 largest heads. For particulars see Circular.

Egyptian, East Indian, or Pearl Millet.

This new Millet is quite distinct from all other species, and is without doubt destined to take a place in the front rank of valuable forage plants. Cows, horses, and other stock are exceedingly fond of this kind of millet, eating it with as much avidity and apparent relish, as they do the green leaves of Indian corn. One pound will sow an acre. Price, 25 cts. per packet; 5 packets, \$1; per lb., \$3.

Prickly Comfrey.

Descriptive circulars with directions for culture, mailed to all applicants.

Prickly Comfrey is specially adapted for the feeding and fattening of stock, and for increasing the milk of cows; it grows more rapidly and luxuriantly than any other green soiling plant, producing on a given space a far greater quantity of forage than any crop now grown. Good grass land yields but 8 tons of grass to the acre, chf green; Lucern, 40; Rye Grass, 50; Vetches, 20; Comfrey, 80 to 120 tons. 4,000 sets will plant an acre.

We will supply roots of the above at the following prices, post-paid, by mail: 4 ounces, 75 cts.; 8 ounces, \$1.25; one lb., \$2.00; 4 lbs., \$7.00.

One pound of the roots will make 175 strong cuttings.

A NEW EARLY PEA.

BLISS' AMERICAN WONDER.—A cross between the Champion of England and Little Gem—combining the good qualities of both varieties, but is earlier and more productive.

¼ Pint packages, 25 cts; Pint, 75 cts., by mail, post-paid.

EARLY LIMA BEAN.

A careful trial of this variety the past season proved it to be ten days earlier than the ordinary variety. 25 cts. per packet. Pint, \$1.00, by mail, post-paid.

Dioscorea Batatas—Chinese Yam.

One of the most valuable esculents in cultivation, though but little known. A well grown root, two years from the bulbets, will measure 2 feet in length, and 2½ inches in its broadest diameter, and is quite hardy, remaining in the ground over winter without protection. The flesh is remarkably white, and very mucilaginous in its crude state. They may be boiled or roasted, and when cooked possess a rice-like taste; are quite farinaceous, nutritive, and valuable for food. It is also a very desirable climbing plant, suitable for covering screens, doors, and unsightly places. It is sometimes called "Cinnamon Vine," on account of the peculiar odor of its blossoms. Small bulbets, in packets of one dozen, 25 cents; 5 dozen, \$1.00; 1 year-old roots, \$2.00 per dozen; \$12.50 per 100.

Kenney's Early Amber Sugar Cane.

In this variety we have a plant that is destined to prove of immense value to the northern portions of our country. Its saccharine qualities are of the first order, fine and rich, and its earliness highly recommend it to the whole country. It stands up well, does not easily blow down. When planted early in May, the seed almost invariably ripens, thus giving one the advantage of a double crop in one year, from one planting, some 20 or 25 bushels of seed, and 150 or more gallons of fine syrup per acre—that is, if it is skillfully handled. All kinds of farm stock are fond of the seed. We have seen sugar produced from this variety equal to the best coffee sugars in the market. By mail, 75 cents per lb.

THE subscriber has on hand and offers for sale a large quantity of **PURE JERSEY WAKEFIELD** and **FOLLETS BRUNSWICK CABBAGE PLANTS.** Wanted in cold frames. Orders by mail or in person will be promptly attended to. Price, \$6 per Thousand.
ALBERT S. WALKER, South Portsmouth, R. I.

Moreton Farm Seeds.

Harris' American Yellow Globe Mangel Wurzel.—I have grown my own Mangel Wurzel seed for several years, selecting a few of the very best and choicest bulbs annually, from many thousand bushels. It is seed such as is rarely offered for sale. I can confidently recommend it. Price, 4 oz., 20 cents; one lb. 75 cts.; 1½ lbs., \$1.00; 4 lbs. \$2.50. Sent, pre-paid, by mail. 10 lbs., or over, by express, at 50 cents per pound.

Blood Turnip Beet.—Same price as above.
Yellow Danvers Onion Seed.—I have grown this variety of onions for fifteen years. The seed I offer was grown by myself in 1877, from very carefully selected bulbs. I can confidently recommend it. Price, 4 oz. 40 cts.; 12 oz. \$1.00; 4 lbs. for \$5.00. Sent pre-paid by mail.
Whethersfield Red Onion Seed.—\$1.00 per pound.
Early Jersey Wakefield Cabbage Seed.—Ounce 30 cents; 4 ounces \$1.00.

Stone Mason Cabbage Seed.—Oz. 25c.; 5 oz. \$1.00.
Six-Rowed Barley.—One dollar per bushel. Bags 10 cents per bushel extra. 20 bushels, or more, including bags, \$1.05 per bushel.

Seed Potatoes.—Early Vermont, Snowflake, Brownell's Beauty, Compton's Surprise, Genesee Co. King, White Peachblows, and Thorburn's genuine Late Rose, \$5.00 per barrel. My stock of Late Rose was obtained direct from Mr. Coy, the originator of this valuable variety. It will, on good land, yield double the crop per acre of Early Rose. Wholesale price on application. Address **JOSEPH HARRIS,** Moreton Farm, Rochester, N. Y.

Broom Corn Seed.

Mapes' Complete & Special Manures,

PREPARED FROM

Peruvian Guano, Pure Fine Bone, dissolved in Sulphuric Acid, Nitrate of Soda, Sulphate of Ammonia, Dried Blood and Flesh, and Potash Salts.

These manures are not only composed of materials which in themselves rank the highest as sources of plant-food, but contain them in the proportions, which practical experience has demonstrated to be best adapted to the wants and habits of **EACH CROP**. They require no other manure, and improve the condition of the land for subsequent crops.

Analyses and full Directions for Use accompany each Package.

Mapes' Corn Manure.

Ammonia 4.50 per cent, Phos. Acid 10 to 12, Potash 6 to 7.
For 50 bushels shelled corn use 3 bags, 400 lbs.
" 75 " " " 5 bags, 1,000 lbs.
Price per ton, \$49.50—per bag (200 lbs.), \$5.20.

Potato Manure (Ville Formula).

Ammonia 4.50 per cent, Phos. Acid 5.97, Potash 13.64.
For 200 bushels Potatoes use 3 bags, 400 lbs.
" 300 " " " 600 lbs.
Price per ton, \$51.94—per bag (200 lbs.), \$5.40.

Mapes' Grass and Grain Spring Top-Dressing.

Use one to two bags per acre for top-dressing winter grain or grass lands—also for hoed crops in hills or rows for producing rapid growth.
Price per ton, \$51—per bag (200 lbs.), \$5.35.

Mapes' Complete Manure.

Ammonia 6 to 7, Phos. Acid 10 to 12, Potash 3 to 4.
A general manure—a substitute for stable-manure—especially adapted for grain crops and grass lands—on soils requiring more Phos. Acid than Potash.
Price per ton, \$50—per bag (200 lbs.), \$5.25.

Mapes' Fodder Corn Manure.

Price per ton, \$49—per bag (200 lbs.), \$5.15.

The above prices include cartage, excepting when total quantity ordered is less than half a ton, then add 50 cents for cartage. Address

THE MAPES FORMULA & PERUVIAN GUANO CO., 153 Front St., N. Y.

PERUVIAN GUANO.

Imported direct from Peru, by

HOBSON, HURTADO & CO.,

AGENTS OF THE GOVERNMENT OF PERU,

No. 63 Pine St., New York.

No. 1 Peruvian Guano—10 p. c. Ammonia Standard.
No. 1 Peruvian Guano—Lobos.

The "Lobos," containing 6 per cent Ammonia, 15@20 per cent Phosphoric Acid, and 3@5 per cent Potassa, is the best and cheapest general Fertilizer in the market, being admirably adapted for Cereals, Corn, Root Crops, Sugar Cane, and Cotton.

Circulars sent free on application.

CHAPMAN & VAN WYCK,

(Established 1819),

DEALERS IN PERUVIAN Guano

EXCLUSIVELY,
170 Front Street,
New York.

Soluble Pacific Guano.

The Superior excellence of this Guano has been so successfully demonstrated during the past ten years in the Middle and Southern States, on cotton, corn, tobacco, sugar-cane, and garden vegetables—the Company's sales having exceeded the enormous aggregate of 35,000 tons in a single season—that it is now offered for sale with entire confidence as to its merits. No fertilizer ever introduced in this country, has undergone severer tests, or come out of them with its character as a first-class, reliable fertilizer more thoroughly established. In consequence of the satisfactory results of these very complete tests, this Guano has acquired a reputation equal to that formerly enjoyed by Peruvian Guano. It is rich in Bone Phosphate of Lime, finely ground (a large proportion of which is immediately soluble), Ammonia, and Potash, besides other ingredients valuable as plant-food, manufactured at the Company's works, Woods Hole, Mass., and Charleston, S. C., under the supervision of competent chemists.

PACIFIC GUANO CO., BOSTON.

E. & O. WARD, PRODUCE COMMISSION MERCHANTS.
POULTRY, GAME, BUTTER, &c., &c.

Also Agents for Hornby's Steam-cooked Wheat and Oats.
No. 279 Washington-st., N. Y.
(Est'd 1845.) Ref. Irving National Bank, New York City.

Complete Manure (Ville Formula).

Ammonia 7.69, Phos. Acid 5, Potash 7.59.
For use the same as Mapes' Complete Manure, but adapted more particularly to light lands, or such as require more Potash than Phosphoric Acid.
Price per ton, \$52.28—per bag (200 lbs.), \$5.50.

Mapes' Beet & Mangold Manure

Price per ton, \$52—per bag (200 lbs.), \$5.45.

Mapes' Fruit and Vine Manure.

For Trees of all kinds, Small Fruits, Grape Vines, Strawberries, etc. Price per ton, \$35—per bag (200 lbs.), \$3.70.

Mapes' Cauliflower and Cabbage Manure.

Price per ton, \$49—per bag (200 lbs.), \$5.15.

Mapes' Lawn Top-Dressing.

For Lawns, Croquet Grounds, Grass Plats, etc. 100 lbs. for 2,500 sq. feet.
Price per ton, \$60—per bag (200 lbs.), \$6.30—per bag (100 lbs.), \$3.50.

Mapes' Spring Wheat Manure.

Very quick in its action—a complete manure for Spring Wheat.
Price per ton, \$50—per bag (200 lbs.), \$5.25.

Prepared Castor Pomace,

for ammoniating Composts, Tobacco, &c.—guaranteed 7 per cent Ammonia, see page 96, March Am. Agriculturist.

Cabbage Growers

and all Gardeners will find my new work on "Vegetable Plants" indispensable, as it gives explicit directions for growing all kinds of plants in open ground and under glass, also more valuable information on noxious insects than was ever before published. Dr. F. M. Huxamer, of New Castle, N. Y., says: "Many a single page contains more valuable hints than could be obtained for ten times the cost of the whole book." On receipt of \$2.50 I will mail one copy of this book and one pound of the finest and best Premium Flat Dutch Cabbage Seed you ever saw! In support of this assertion I will send testimonials from many eminent Horticulturists, and a sample of the seed free to any address.

ISAAC F. TILLINGHAST,
Late TILLINGHAST BROS.,
Factoryville, Wyoming Co., Pa.

CROSMAN BRO'S CATALOGUE & GUIDE, to the Flower and Vegetable Garden, for 1878. Elegantly Illustrated. Sent FREE. Address
[Established 1840.] **CROSMAN BRO'S**, Rochester, N. Y.

My Annual Catalogue of Vegetable and Flower Seed for 1878 will be ready by January, and sent free to all who apply; Customers of last season need not write for it. I offer one of the largest collections of vegetable seed ever sent out by any seed-house in America, a large portion of which were grown on my six seed farms. **Printed Directions for cultivation on every parcel.** All seed sold from my establishment warranted to be both fresh and true to name; so far that should it prove otherwise, I will refill the order gratis. As the original introducer of the Hubbard and Marblehead Squashes, the Marblehead Cabbages, and a score of other new vegetables, I invite the patronage of all who are anxious to have their seed fresh, true, and of the very best strain. **NEW VEGETABLES A SPECIALTY.**

JAMES J. H. GREGORY, Marblehead, Mass.

No Advertisement of Medicines or Humbugs received. Address all orders to

ORANGE JUDD COMPANY,
245 BROADWAY, NEW YORK.

containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from p. 129.

Oyster Shell Lime.—"B." Oyster shell lime is a very pure kind of lime containing a small percent of phosphoric acid and no magnesia; it is therefore worth a little more than stone lime. The price depends upon the facility for gathering the shells and the cost of fuel. It will pay for use at 10 to 15 cents a bushel.

A Tonic for Pigs.—"C. A. F." Reno Co., Kansas. A good tonic for hogs is made as follows: Take 5 pounds of linseed meal, one pound of charcoal, 4 ounces of gentian root powdered, 4 ounces of sulphate of copper, one pound each of flowers of sulphur and of salt. Mix, and give a tablespoonful in the feed occasionally.

Cow Leaking Milk.—"W. H. D." New Preston, Conn. There is no cure for a cow that leaks milk. This fault arises from a laxity of the muscular stricture which closes the duct of the teat, and is therefore beyond remedy. To bother with devices to prevent it would cost more than the loss arising from selling the cow for beef, and procuring another.

Planting Beans.—"B. W. Y." New Castle, Pa. A light soil is best adapted for beans, but any soil that is well prepared, dry, and mellow, will produce a fair crop. The usual method of planting is in rows 24 to 27 inches apart, and the beans 6 inches apart in the rows, or in hills 18 inches apart. From two pecks to a bushel of seed is needed for an acre.

Meeting of Stock Graziers in Colorado.—The 8th annual meeting of the Colorado Growers' Association, was held at Denver, Jan. 8th. The importance of this interest was clearly set forth in the course of the proceedings. The members of the Association represent 600,000 head of cattle, a capital of \$10,000,000, and employ more than 2,000 men. The shipments eastward the past season have been 100,000 head, worth \$3,000,000. These cattle now fully occupy the grazing lands of the whole State, and the importance of securing a steady and staple foundation for this interest, is unquestionable. At present the stockmen hold their grazing grounds by possession only, the peculiar condition of the tenure of the lands and the laws regarding their sale, practically prohibiting ownership or legal right to occupation. We have frequently pointed out this anomalous and injurious condition of things, and hope that very soon some change in the law will be made, by which the absurd restriction of 160 acres to each purchaser, of lands that are totally useless for agriculture, may be abrogated; and some method may be found of leasing large tracts or selling them at reasonable prices for pastures only.

The Value of Mixed Food.—"G. C. C." When straw, or other fodder of inferior value, is fed along with some rich concentrated food, as corn, oil cake, bran, etc., in proper proportions, the mixture can be made of equally nutritious value with good, medium, or the best hay, so that by adding to the straw the needed equivalent, we can make a good substitute for the hay. The proper proportions can be gathered from Professor Atwater's articles on feeding stock in former numbers.

Catalogues Received.

When we gave such ample space last month, we supposed that we had finished up our catalogue list for the season. Since then, a large number have come to hand which have equal claims upon us with the others, and we give them here. When there are several departments

embraced in one catalogue, we, as before, place it under the head of what appears to be the leading business.

NURSERYMEN.

The number of nursery establishments that add a floral department to their nursery business is annually increasing, but we can not record these under distinct heads, unless separate catalogues are issued.

J. W. ADAMS, Springfield, Mass.—A general fruit and ornamental stock, with Worden grape as a specialty.

EDWIN ALLEN, New Brunswick, N. J., an abridged, well-selected list of fruit and ornamental trees, by an excellent pomologist.

ROBERT BUIST, Philadelphia, Pa., though most generally known as a florist, has an ample fruit and ornamental tree and plant catalogue.

BUSH, SON & MEISSNER, Bushberg, Jefferson Co., Mo.—Their price list of grape vines is as full, compact, and instructive as usual.

HARVEY CURTIS, Owego, N. Y.—General nursery stock. A HANCE & SON, Red Bank, N. J., send both retail and trade lists of a large and most varied stock, including a number of specialties and novelties.

HEIKES NURSERIES Co., Dayton, Ohio.—Semi-annual trade list of general stock.

HOOPES, BROTHER & THOMAS, Westchester, Pa.—Trade list, offering favorable terms to wholesale buyers. T. S. HUBBARD, Fredonia, N. Y.—A wholesale list of grapes, etc., with wood for propagating.

THOS. JACKSON, Portland, Me.—Wholesale catalogue of general stock. Very full in Evergreens.

J. JENKINS, Winona, Ohio, makes \$1.00 collections of fruits and ornamental plants a specialty.

W. W. JOHNSON, Central Lake, Austin Co., Mich.—Forest-tree seedlings, with notes on planting; also forest-tree seeds.

SAMUEL KINSEY, Dayton, Ohio.—Small fruits in large variety; also ornamental plants.

LAPHAM & ANTHONY, Clayton, Del., call theirs the Dollar Nursery, as they send plants in \$1 collections.

WILLIAM H. MOON, Morrisville, Pa.—General fruit-list; very full in ornamental plants.

PARSONS & SONS Co., Flushing (L. I.), N. Y.—A special list of "New and rare plants." A remarkably choice collection, few of which are to be found elsewhere.

WM. A. STRONG & Co., Brighton, Mass.—A general catalogue with a list of new and desirable varieties.

F. TROWBRIDGE, Milford, Conn.—A cranberry catalogue, with directions for growing.

T. C. THURLOW, Newburyport, Mass.—General list, and a special one of evergreens.

E. R. UNOERHILL, Poughkeepsie, N. Y.—Small fruits, with novelties, especially in strawberries.

HENRY WILBUR, Montgomery, Mich., sends three lists; fruits in general, peaches, and ornamental shrubs, etc.; each with a full cultural treatise.

SEEDSMEN.

BEACH, SON & Co., No. 7 Barclay St., N. Y., in the "American Garden," continued as a quarterly, offer their stock, and give much useful and timely instruction.

PAUL BUTZ & SON, New Castle, Pa.—List of tested garden, field, and flower seeds.

W. H. BURLING, Plainfield, Conn.—A general list of seeds and plants, and a special list for market gardeners. J. H. & W. E. CONE, Hartford, Conn., offer genuine Wethersfield garden-seeds, implements, etc.

CURTIS, COBB & WASHBURN, Boston, Mass.—The former firms of Curtis & Cobb and Washburn & Co. have united their forces, and the result is an immense catalogue, full in every department.

HENRY A. DREER, No. 714 Chestnut St., Philadelphia, Pa., presents in one compact catalogue a full stock of seeds of all kinds, implements, and florists' supplies, also a large list of greenhouse and other plants.

HAWKINS & CORNISH, Goshen, Orange Co., N. Y.—General seed stock; potatoes a specialty, with kinds not offered elsewhere.

HOVEY & Co., No. 16 South Market St., Boston, Mass.—A full catalogue, with a long list of novelties, as usual.

E. B. JENNINGS, Southport, Conn.—Choice potatoes and seeds of his own growing.

A. W. LIVINGSTON'S SONS, Reynoldsburg, Ohio.—General seed list, with specialties of their own.

THOMAS MEZHAN, Germantown, Pa.—Special list of fruit seeds, kept in condition for spring planting.

A. C. NELLIS, Canajoharie, N. Y.—Seeds, vegetable plants, greenhouse plants, and bulbs.

GEO. W. PARK, Mt. Vernon, Ohio, offers a general stock of seeds, bulbs, etc.

FRANK S. PLATT, New Haven, Conn.—In liberal size, large type, fine paper, and excellence of illustration, this catalogue is something remarkable; and its matter seems to be as good as its manner.

W. H. SPOONER, Boston, Mass., preserves the same neatness and compactness which have heretofore made his very full catalogue noticeable.

ROBERT VEITCH & SON, New Haven, Conn.—A general wholesale seed list.

JAMES VICK, Rochester, N. Y.—Besides the ample general catalogue noted last month, sends a special wholesale list.

FLORISTS AND DEALERS IN PLANTS AND BULBS.

C. E. ALLEN, Brattleboro, Vt., in addition to greenhouse and bedding plants, offers seeds and small fruits.

BELLEVUE NURSERY Co., Paterson, N. J., with their usual full stock, offer several novelties. Also seeds.

P. J. BERCKMANS, Augusta, Ga., besides carrying on an immense nursery, has an extensive florist's establishment, and offers, besides others, many plants suited especially to the Southern States.

ROBERT BUIST, Sr., 67th St. and Darby Road, Philadelphia, Pa.—That this establishment, now nearly half a century old, still keeps up its freshness, is shown by this full catalogue.

PAUL BUTZ & SON, New Castle, Pa., with general stock, offer many novelties.

THOMAS ELVEYSON, New Brighton, Pa., besides a large plant list, has a full seed catalogue.

ELLWANGER & BARRY, Rochester, N. Y., issue a special rose catalogue, which is not a mere price list, but is a readable treatise.

WM. A. HACKETT, Duquene, Iowa, has a full stock, with most of the novelties of the year.

HOOPES, BROTHER & THOMAS, Westchester, Pa., have a special catalogue of greenhouse and bedding plants, and offer many quite new.

M. MICHEL, Bryan, Brazos Co., Texas.—A full stock, with abundant cultural directions adapted to the peculiar climate of Texas.

MAHLON MOON & SON, Morrisville, Pa., send a special catalogue of Gladioli, of which they have one of the largest and choicest collections in the country.

JOSEPH T. PHILLIPS & SON, West Grove, Chester Co., Pa.—A full illustrated list, with directions for cultivation.

JOHN SAUL, Washington, D. C.—We always look to this catalogue for choice novelties, and the present issue does not disappoint. It has a colored plate of the magnificent pelargonium "Mrs. John Saul."

DEXTER SNOW, Springfield, Mass., in issuing a general list, does not forget his old specialty, the Verbena, of which he offers a new set.

CHARLES L. STARR, Avondale, Chester Co., Pa., makes a specialty of carnations, but has a full general list.

J. M. THORBURN & Co., No. 15 John St., N. Y.—A full list of Gladioli, with other spring bulbs; also hardy perennial and small fruit plants.

ROBERT VEITCH & SON, New Haven, Conn., one of the oldest houses in the country, make but little noise, but have the plants, and choice ones.

H. W. WILLIAMS & Co., Galesburg, Ill., are growers of Gladioli, and issue list.

WM. C. WILSON, No. 46 West 14th St., N. Y., and Astoria (L. I.), N. Y., make their catalogue for this year as much a wonder in the way of variety as ever.

WOOLSON & Co., Passaic, N. J., make a specialty of hardy plants, and their list for this year contains many not before offered.

FOREIGN.

J. A. SIMMERS, Toronto, Ont., Canada.—A copious and well-illustrated catalogue of about everything in the way of seeds.

MAX LEICHTLIN, Baden Baden, Germany, sends a catalogue of his remarkable private garden, from which so many choice things have passed into general cultivation.

HAAGE & SCHMIDT, Erfurt, Germany.—A seed catalogue that is immense, for the variety of its contents.

FARM AND GARDEN IMPLEMENTS, ETC.

COLBY & Co., Benton Harbor, Mich.—Fruit packages of all kinds.

CHADBORN & COLDWELL MFG. Co., Newburgh, N. Y., make the Excelsior Lawn-Mower, and, in a beautifully illustrated circular, offer a reduction in prices for both hand and horse patterns of this popular machine.

THOMAS ELVEYSON, New Brighton, Pa.—Terra cotta ware for in-door and out-door use, baskets, vases, etc.

J. R. FITZHUGH, Philadelphia, Pa., makes a hay elevator, which has received many premiums and diplomas at exhibitions and fairs.

GRAHAM, EMLEN & PASSMORE, No. 631 Market St., Philadelphia, Pa., makers of the Philadelphia Lawn-Mower, illustrate and describe the merits of the various forms of their excellent machines in a neat catalogue.

T. B. HUSSEY, North Berwick, Me., offers "Premium Plows," "Centennial" cultivator and reversible cultivator teeth.

U. S. WIND-ENGINE Co., Batavia, Ill., describe a variety of their small haying tools, a very effective grapple-fork, hay-carriers, etc.

IMPLEMENTS.

THE NEW YORK PLOW Co., New York, give descriptive illustrated circular of their specialties, among which are several makes of Adamant plows, with movable and reversible points, root-cutters, and other implements.

MERRIMAC MACHINE Co., Newburyport, Mass., describe a seed-sower wholly of iron, for onion and other seeds.

DAIRY APPLIANCES.

CORNISH & CURTIS, Fort Atkinson, Wis., supply the Whipple Rectangular Churn, which has no dasher.

AUGUSTUS REEVE, 31 Market street, Camden, N. J., has a porous earthen butter-cooler, which, having tried, we find keeps butter cool and hard, when placed in a warm place. It is an evaporating refrigerator.

HENDERSON & Co., Philadelphia, make the Lilly butter-worker, which is intended for the storckeeper and butter-dealer, as well as for dairymen.

MOSELEY & STODDARD, Poulney, Vt., keep a full supply of all sorts of dairy furniture and tools, and issue an illustrated pamphlet descriptive of them.

MISCELLANEOUS.

GEO. D. BISSELL & Co., NAUGATUCK, Conn., send a catalogue of their "Little Washer."

G. J. CAPEWELL & Co., Cheshire, Conn., in their catalogue of "Light Hardware," offer the greatest variety of "Notious and Crinkums," from lemon-squeezers to seven-shooters. A curiosity.

FOR \$1.

2 ROSES, 2 DOUBLE Geraniums, 2 Zonale Geraniums, 2 Fuchsias, 1 Heliotrope, 4 Coleus (best), 2 Tuberoses, 2 Gladioli, 2 Tigridias (Shell Flower), 4 Verbenas, 6 Basket Plants, 2 Packages of Flower Seeds, all Good Strong Plants.

Name Paper.

Stockbridge Manures

Originated by Prof. STOCKBRIDGE, Professor of Agriculture in the

MASS. AGRICULTURAL COLLEGE.

40 to 80 Bushels	Corn	per Acre,
25 to 50 "	Wheat	" "
20 to 40 "	Rye	" "
25 to 50 "	Barley	" "
150 to 250 "	Potatoes	" "
1500 to 2100 lbs.	Tobacco	" "
2000 to 4000 "	Hay	" "

and other crops in proportion, have been produced by the use of these manures alone. The results on Corn and Grass are truly wonderful.

A special manure is made for each Farm and Garden Crop, containing the Plant-Food which each particular Plant requires. These manures were used on more than 10,000 acres in 1877, and with Great Success.

Send for Pamphlet for 1878, full of information, mailed free.

MADE ONLY BY

W. H. BOWKER & CO.,

3 PARK Place (opposite the Post-Office),

NEW YORK.

Boston, 43 Chatham Street.

Nothing Better than Stable Manure.

There is nothing better than stable manure, all things taken into account, and the Stockbridge is not intended to displace it; but when the barn manure is all used, and something more is wanted, or when time is short and the crop must be hurried in, or you have a long distance to haul your stable manure, or when you desire to cultivate more land, the Stockbridge may be used and will produce, we believe, equally as good crops, and will be found fully as lasting in the effects if applied to the same extent as stable-dung.

But in comparing them, remember you can put on enough stable-manure "to beat" the Stockbridge, or enough Stockbridge "to beat" the stable-manure. In making trials, do not put ten bags of Stockbridge against one load of manure, or one bag of Stockbridge against ten loads of manure, but apply equal values, remembering the extra expense of hauling and applying stable-manure form a large part of its cost.

Do All Soils Need Complete Manures?

If not, what do they require? Who has ever determined satisfactorily what his soils require? This can not be settled in a practical way; if indeed it can be settled at all. Some one may say chemical analysis of soils will settle it, but this idea was exploded long ago. Another suggests a series of experiments in growing crops, but this is not practicable, for a crop only tells what it has taken out, and not what is left and how much if any of any substance is left in the soil.

Therefore, for the great mass of farmers to determine by their crops what their soils need, is practically impossible, and hence, the only safe way is to apply complete manures. And in using complete manures, is it not more reasonable to use those like the Stockbridge, which have for their standard the analysis of plants, than any made by an arbitrary standard, which has no relations whatever to the plant? So we think, and so do the majority of our customers. Farmers, drop this manuring by guess, and adopt the Stockbridge plan, which is economical, and appeals to your common sense.

Now is the time to make up your order for the STOCKBRIDGE MANURES for all crops, and to

TOP DRESS

your Winter Grain Fields, Grass Lands, and Pastures. The Stockbridge, applied as a top-dressing during this month and a part of next, on Winter Grain, will give most excellent results. Winter Grain which has suffered from the open winter will also be greatly benefited. For top-dressing Grass, the Stockbridge has given universal satisfaction, producing from two to three tons to the acre. Remember it is free from weed seeds, and you can haul, at one two-horse load, enough to go over six or seven acres. It may be applied from now till early May, but those who used it early last season were enabled to cut a heavy crop in early June, and also obtained a good second crop before the August drouth set in.

ALLEN'S PLANET, Jr. HAND SEED DRILLS AND WHEEL HOES

are standard machines; thousands in use; have taken the Centennial, Franklin Institute Silver, Erfurt, Germany, and other medals. Sold either separate or combined: the combined tool (Agriculturist Premium), is greatly improved for 1878. PRICES much reduced. **THE PLANET JR. HORSE HOE**, popular in 1877, is perfected for 1878. Wrought bolted frame, polished cast steel teeth, patent elevators, etc. Our catalogue is FREE. S. L. ALLEN & CO., No. 229 Market Street, Philadelphia, Pa.

PEARCE'S IMPROVED CAHOON BROADCAST SEED SOWER.

Address **BUFFALO, N. Y.**

Serviceable Silver-Plated Ware.

"Silver Steel" and "Albata" Silver-Plated.
Save the retailers and jobbers profit, and buy direct of Manufacturers at Wholesale Prices.

An opportunity is now given to buy any of the silver-plated ware manufactured by us direct. The goods are made of good durable metal and will wear for years.

These are not cheap brass goods, like the so-called "Premium Silver Ware," with which the market is flooded, but are warranted as represented. Remember, brass goods are poisonous!

The entire set (50 pieces).....\$11.00

Since our former advertisements appeared, we have decided to give the readers of the *American Agriculturist* a higher grade of goods than those heretofore advertised. Not that the others did not give perfect satisfaction, but we feel that the new designs (made expressly for this trade) will, in quality and finish, be more desirable, and well worth the small advance in price.

All sums over \$1 should be sent in Registered letter.

Address

STEVENS BROS. & CO.,
Manufacturers, Northford, Conn.

BEATTY

For further information address Whiteley, Fassler & Kelly; Champion Machine Co., and Warder, Mitchell & Co., of Springfield, O., and The Toronto Reaper and Mower Co., Toronto, Canada.

USE THE PERFECT BUTTER COLOR!

WELLS, RICHARDSON & CO. PERFECT BUTTER COLOR is recommended by the agricultural press, and used by the very best Dairymen in this country. Harris Lewis, L. B. Arnold, O. S. Bliss, L. S. Hardin, A. W. Cheever, E. D. Mason, and thousands more. It is far better than carrots, annatto, or any other color, at one-fourth the cost, and no work to use. It gives a pure dandelion color, and never turns red, or rancid, but tends to improve and preserve the butter. A 25 cent bottle colors 300 pounds. Warranted to add 5 cents per pound to its selling value. Ask your Druggist or Merchant for it, or if you would like to know what it is, what it costs, who uses it, and where you can get it, write to **WELLS, RICHARDSON & Co., Proprietors, Burlington, Vt.**

BUTTER COLOR.

After fair trial and severe tests it was awarded Centennial Prize Medal. WHY IT IS SUPERIOR TO ALL. 1st. It has no taste or smell, and is as harmless as water. 2d. It is liquid, and easy to handle, and is mixed in cream before churning. 3rd. It produces a color resembling June Grass Butter. 4th. It is the only article that will color the butter and not the buttermilk. 5th. It gathers all butter materials, increases the weight more than will pay for the color used. It is the best ever known. Send your address on postal card for my receipt book, free. It tells how to make butter, back, cream, and buttermilk. **MRS. B. SMITH, 72 N. 4th St., P. O. Box 1954, Phila., Pa.**

Over 5,000 Now in Use.—The Best MILK COOLER and WARMER IN THE WORLD

FOR RAISING CREAM.

Can make butter all seasons of the year. Will make twenty-five per cent more butter, fifty per cent better butter, with seventy-five per cent less labor, by using the IRON-CLAD MILK PANS, with great improvements for 1878. Made for any sized dairy, from five to five hundred cows. Estimates given for furnishing creameries. For Circulars, Price List, &c., address **BUNNELL & BROWN,** (Patentees and Manufacturers, and General Dealers in Dairy Implements.) **Guilford, Chicaugo Co., N. Y.**

CHOICE BUTTER.

(From Massachusetts Agricultural College Farm.) "AMHERST, MASS., Feb. 9, 1878. VERMONT FARM MACHINE COMPANY: We are so well pleased with the Cooley Creamer that I feel bound to say a word in its favor. It takes us only twenty minutes to churn, and the extra yield of butter is wonderful. I have cheerfully recommended it to the Japanese government above all other systems. Yours very respectfully, A. A. SOUTHWICK, Farm Supt." Address for circular, **Vt. Farm Machine Co., Bellows Falls, Vt.**

Improved Butter Tubs and Coolers,

with movable Ice Chambers. Best in the market. Arc made in 12 different sizes, of white Cedar, bound with galvanized iron or brass hoops. Within the tub is fitted a tin Cooler, having a movable Chamber for ice at each end. On the tin is constructed a series of ledges, on which rest the shelves for supporting the butter; suitable for round, half-round, and square prints or rolls. Can be locked for shipping. Will keep butter in good order from 18 to 24 hours. Capacity from 12 to 300 lbs. Price from \$3 to \$25. **J. G. KOEHLER, Manufacturer, 503 North 2nd St., Philadelphia, Pa.**

BUTTER WORKER.

The most effective, simple and convenient yet invented. Works 30 lbs. in less than 5 minutes, thoroughly working out buttermilk and mixing the salt. **AGENTS WANTED.** Send for circular. **A. H. REID,** 6 N. Eighteenth St., Philadelphia, Pa.

FARMS

in the best part of MARYLAND at great bargains. For catalogue and prices address Manacha & Gibson, Centerville, Md.

WILLIAM CROZIER has much pleasure in calling the attention of Cow-keepers, Farmers, and Dairymen to the NEW SELF-MILKING APPARATUS. This Apparatus or Cow Milker has been tested by a large number of practical Agriculturists, Dairymen, &c; and, without exception, merited high encomiums and commendations, for its adaptability and wonderful rapidity in the Milking of Cows. It is considered one of the most invaluable and useful Machines yet invented.

Amongst its many advantages are—
 1st—It is SELF-ACTING, easy of application; and can be used by any person, however ignorant of Milking.

2nd—It will Milk any Cow in FOUR Minutes effectually, and its use is more agreeable to the Cow than Hand-Milking.

3rd—It is a great boon in the case of Sore or Corded Teats.

4th—Its Usefulness, Simplicity, Saving of Time, Cleanliness, Durability, and Cheapness, prove it to be a most important and necessary adjunct to a Dairy, and it has only to become better known to be universally used.

Sent free on receipt of Post Office order for \$5.

Printed Instructions accompany each Machine.

MILK TUBES.

COW-KEEPERS should not be without one of these, as they are invaluable for sore or Corded Teats.

PRICE \$1.00 each.

WM. CROZIER, Northport, L. I., N. Y.

ORANGE JUDD COMPANY,

245 BROADWAY, NEW YORK.

A Trochar for Cattle-Men.

In June of 1872 we gave illustrations of a Trochar and Canula to be used in ringing a bull, and on page 13 (January) and page 97 (March) of the *American Agriculturist* for 1873 (copies of which may be got from this office for 15 cents each) we described the use of this apparatus in relieving hoven in cattle. These articles have brought out a large demand for Trochars, and failing to find just the right kind among the makers of surgical implements, we have induced an establishment to undertake their manufacture. We give herewith a small engraving of the Trochar. These articles are now in the trade, and may be had of most dealers in agricultural implements. Those who can not get them from dealers can receive them from this office, prepaid, for \$1.00.

ORANGE JUDD COMPANY, 245 Broadway, N. Y.

A COPPER BULL-RING,

$2\frac{1}{2}$ inches in diameter, of the most approved pattern, with screw-driver for putting it together, will be sent, prepaid, on receipt of \$1.00. Address

ORANGE JUDD COMPANY, 245 Broadway, N. Y.

CHEESE AND BUTTER MAKERS' SUPPLIES

AND COMPLETE
MANUFACTURING OUTFITS,
FURNISHED BY
WHITMAN & BURRELL, Little Falls, N. Y.
AT STILL LOWER PRICES.

We received the highest awards for the best Cheese and Butter Apparatus at the late great Cheese and Butter fair, held at Chicago, Ill., with cash prizes amounting to \$135.00.
We are sole manufacturers of the HUBBELL GANG CHEESE PRESS, which took the first prize at this fair. This is the only Press that has right to use the **bandager**, all others subject to royalty of \$4.00 per hoop.
Our **ECONOMIZER BOILERS**—with and without Engines—both portable and stationary, will make more steam from less fuel than any other Horizontal Boilers built. **Price very low.**
The Economizer Boilers are manufactured for us (in duplicate parts), under United States patents, by Porter Manufacturing Company, thus securing perfection and uniformity.
Our **New 600 Gallon Refrigerator Vats**, for setting milk for cream and afterward making the milk into cheese in same vat, received highest prize at the Chicago fair.
Our **Latest Improved Patent Knife Curd Mill** is recommended by the best cheese makers in the land.
We are first hands with greatly reduced prices also for **Rennets, Annattoine, Annatto, Bandage, Seale Boards, Liquid Rennet Extract, imported dry Extract of Rennet, &c.**—General Agents for all dairy districts for the **Genuine Ashton Salts.**
All correspondence answered promptly. Circulars and prices furnished freely.
The **O'Neil Self-heating Vats** at prices less than ever before.

WHITMAN & BURRELL, Little Falls, N. Y.

STEAM ENGINES, A. B. FARQUHAR, York, Pa.,

Cheapest and best for all purposes—simple, strong, and durable. Also **Traction Engines** for common roads.

SAW, GRIST AND RICE MILLS, GINS, PRESSES AND MACHINERY generally. Inquiries promptly answered.

Fig. 1. Vertical Engines, with or without wheels, very convenient, economical, and complete in every detail, best and cheapest Vertical in the world. **Fig. 1** is engine in use. **Fig. 2** ready for road.
The Farquhar Separator (Warranted) Feeds Agricultural Works, York, Pa. Lightest draft, most durable, simplest, most economical and perfect in use. Wastes no grain, cleans it ready for market.
Send for Illustrated Catalogue. Address A. B. Farquhar, York, Pa.

GARDENER'S PITCHING APPARATUS.

FORK READY TO ADJUST IN HAY.

Fig. 2.

For unloading hay, grain, etc. Now is a good time to put it. Send for circular. This circular gives you valuable information.
E. V. R. GARDENER & CO.,
Johnson's, Orange Co., N. Y.

Farmers Friend Grain

And Fertilizer Drill.

The quantity is regulated with gear-wheels in a **CONE**, so there are no loose wheels or movable feeders, and it will sow any grain perfectly and accurately.
It has the best **Spring Hoe**, and every Drill has a **Force-Feed Grass-Seeder, Patent Shifter, and Surveyor** free.
Illustrated Catalogues, with description, prices, and a **Full Centennial Report**, sent on application. Agents wanted in unoccupied territory. Address, stating where you saw this notice,
FARMERS' FRIEND MANUF'G CO.,
Dayton, Ohio.

MONEY Made rapidly with Stencil and Key Check Outlets. Catalogues and Samples FREE. S. M. SPENCER, 112 Washington St., Boston, Mass.

THE GLOBE NAIL. THE BEST HORSE SHOE NAIL EVER MADE.

About ten years ago the **GLOBE NAIL COMPANY** of Boston, put on the market the first pointed, polished and finished Horse Shoe Nails ready for driving. Previous to that time all Horse Shoe Nails were pointed, and most of them made, by the shoers in their own shops at the rate of but six pounds per day.

The **Globe Nail** was at once found to be much cheaper and better than any then in use. It soon became so popular that all manufacturers of Horse Shoe Nails were compelled to make their Nails to resemble the **Globe**. For the last ten years it has been the model. Each year the Nail has been greatly improved in quality, and to such a point have we educated the shoers that now they will hardly use a nail unless it is absolutely perfect.

600 lbs. Finished Nails per day.

At the Centennial Exposition in Philadelphia, we were awarded the Medal and the following report, far stronger than that given upon any other Nail:

INTERNATIONAL EXHIBITION, 1876.
U. S. CENTENNIAL COMMISSION.

[BUREAU OF AWARDS.] PHILADELPHIA, June 22, 1876.
No. 239, **Globe Nail Co., Boston, Mass.**

Horse Shoe Nails, Pointed, Polished and Finished. The uniformity in size, smoothness of finish, hardness and tenacity of the iron, closeness of fibre, and excellence of the head and point, the tensile strength of body, and riveting properties of these Nails, unite in making them of the very highest class of manufacture.

Recommended for an Award of Merit.
DANIEL STEINMETZ, Phila., Chairman,
J. D. IMBODEN, Richmond, Va.,
CHARLES STAPLES, Portland, Me.,
G. L. REED, Clearfield, Pa.,
J. A. V. McARDY, Aberdeen, Scotland,
T. DIEFFENBACH, Germany.

Group Judges XV.

We annex a sample of the testimonials we receive daily from all parts of the country:

St. Louis, Mo., June 8, 1877.
GLOBE NAIL CO., Boston, Mass.
Gentlemen: Find enclosed advertisement and postal card concerning your Nail. [Referring to a scurrilous advertisement and postal card, disparaging the **Globe Nail**, circulated by a rival manufacturer over the humane signature of "Humane Society for the Prevention of Cruelty to Animals." No Society bearing that title ever existed.] As I take a great interest in the prevention of cruelty to animals, horses in particular—I desire to say a few words in favor of **The Globe Nail**. Though I am not a very extensive Horse Shoer, yet I have used enough Nails of the different makes to speak knowingly. I have used the **Globe Nail** in my shop and on the race track for six years, on all classes of horses, from the heavy draft horse to the tender footed running horse; and I can safely say it has no superior in point of **Toughness, Shape, and Finish**, if it has any equal. I have used about fifteen hundred pounds of **Globe Nails** a year for the last six years, and in that time I have found four imperfect Nails, two of which I returned to you about two years ago and received in return four perfect ones, for which accept my thanks. If my men had no better sense than to drive those imperfect Nails in a horse's foot, I would not consider it the fault of the Nail if the horse was lamed. If bosses would look more to the competency of their men and less to trying to get shoeing nails a few cents a pound cheaper, we would have fewer lame horses. I know for safety and durability, with a man who understands his business to drive them, your Nails can't be beat! I am willing to pay, without any suit, for all horses that are lamed in my shop by using the **Globe Nail**. As long as it is made as at present, I shall continue to use it, even if I could get other Nails for nothing. I consider it the safest Nail that was ever driven in a horse's foot.

Yours Very Respectfully,
(Signed),

P. H. O'NEILL,
Horse Shoer, No. 1007 Broadway.
P. S.—I think I could get every boss in St. Louis to sign this if I thought it necessary.

The best Horse is sure to win. SO
CLEAR THE TRACK FOR THE
GLOBE NAIL CO.

MAY, 1878.

THE

"Model Piano."

PRICE \$150 to \$200.

The "MODEL" is a beautiful little Upright or Cottage piano; it is manufactured from the best materials that can be procured; the workmanship is excellent, and its durability is guaranteed; it is small, light, and occupies but little room, is easily transported, and above all the "MODEL" is sold at about one-third the price that is usually paid for any other reliable piano. For the above reasons, it is very suitable for people of moderate means, and those living in small houses; but it is especially adapted for beginners, and on account of its low price, commends itself to every parent, because it possesses all the principal features of the finest piano, and has none of the numerous disadvantages of the reed organ.

THE CHAMPION COMBINED MOWER AND SELF-RAKING REAPER.—Drawn and Engraved for the American Agriculturist.

Until recently, combined reapers and mowers have been considered unsatisfactory machines, and farmers have been to some extent prejudiced against them. This has been unfortunate, because few farmers can afford to buy two machines to perform two similar operations, when one could be made to serve the purpose. But after six years of successful work it has been proved that the mechanical difficulties in the way of the effective operation of a combined machine have been vanquished by the manufacturers of the machine of which we give the above illustration. This is the Champion Combined Self-raking Reaper and Mower, made at Springfield, Ohio. The character of the machine is readily apparent from the engraving, and the full details, which show the reaping-machinery added to the mower, are given on another page. At figure 1, on page 168, the mower is shown so clearly, that there can be no mistake about the parts, and at figure 2 the added apparatus is so shown, that the operation of the combined machine

is equally clear. It is needless to say anything in regard to the reputation of the Champion machines. The name is familiar to every farmer, who has seen or heard of mowers and reapers, and the fact that 35,000 of these machines are made annually in the workshops of the Company—the largest manufactory of agricultural implements in the world—evidences the estimation in which they are held. In regard to awards for excellence at exhibitions, the Champion machines have stood in the front rank of those exhibited. It took five first premium medals at the Centennial Exhibition, and an award of five diplomas for the finest exhibit in the Hall and for merit in the great field trial held in connection with the Centennial. At this trial the Champion machine recorded the remarkably light and hitherto unexampled draft of only 131 pounds. It also succeeded in cutting perfectly grass that had been beaten and laid by storms, and in addition, to make the test more severe, had been flattened by a heavy roller drawn over it. No severer test than this could be

imagined. As a reaper it cuts the grain successfully, although it may be laid and tangled in the worst manner, and delivers it in good and even gavels ready for binding. These two important operations are accomplished equally well, and the change from mower to reaper or back again can be made with ease in twenty minutes. Clover-seed and flax may also be successfully harvested with it. The catalogues of makers of first-class machinery are publications of high excellence, and serve a purpose beyond mere advertising. To this the catalogue describing the Champion is no exception, as the machine is shown in action in its various combinations and positions, including its appearance on the road, while every detail of machinery is given with such distinctness and accuracy, that one at all acquainted with mechanics can, by a study of the catalogue, understand the construction of the machine, and form an opinion of its working in the field, almost as well, as from an actual inspection of the thing itself.

AMERICAN AGRICULTURIST.

NEW YORK, MAY, 1878.

Hints for Work.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every paper, from the latest experience and observations, by practical men in each department.]

Corn Planting.—Over a large portion of the country the planting of corn begins with May. Although early planting is convenient, and in some cases unavoidable to prevent stress of work, yet with corn it is a question if anything is saved by hurrying it into the ground. The first operation, that of

Plowing Sod Ground, we generally postpone until ready to plant, so that the seed may go into fresh mellow soil, and the clover grow as much as possible. With fallow ground this may not apply.

Manure for Corn.—Corn is a gross feeder, and fresh manure is acceptable to it. Where the sod has been top-dressed early in the spring, and the manure turned under with the vigorous growth of herbage, no better preparation can be made for this crop. Then after harrowing, a light dressing of some active artificial fertilizer, guano, blood-manure, fish scrap; or either of the special corn manures may be given broadcast, or in the hill. When the sod has not been previously fertilized, the manure, if coarse, may be spread upon it and plowed under, or, if fine, may be harrowed in. When no stable-manure can be had, a liberal dressing of

Artificial Manure, of some kind, should be used for the corn crop. It is very certain that an improved agriculture must be based upon the use of this kind of fertilizers; because, as we can not help taking something from the soil which, under the best system can not be returned to it, it becomes necessary for us to find something to replace the loss. This we may do by purchasing five or ten dollars worth per acre of artificial fertilizers, and gaining twenty or thirty dollars worth of extra product in the crop. Fertilizers, well applied, can be made to return their cost, and a hundred per cent profit; and this ought to be satisfactory.

How to Use Fertilizers.—Many chemical fertilizers are highly concentrated, and should not be brought into close contact with the seed. We are using several tons of these fertilizers the present season, and apply them in the following way:

About two-thirds is sown broadcast on the harrowed soil, and one stroke of the harrow is then given to mix soil and fertilizer together. The seed is then drilled, or planted, and the other third is then scattered evenly upon the surface. In this way a very thorough mixture is secured.

The Quantity to be Used.—After many experiments last season, we have fixed on 500 to 600 pounds per acre, where no other manure is used, and 200 to 300 when the soil does not need a full dose. It is not wise to half feed the soil, any more than to half feed an animal.

Choice, and Preparation of Seed.—No plant is more improved by choice of seed, and careful cultivation, than corn. For some hints on this subject, see article last month. To deter birds from pulling the seed, and cut-worms from nipping the sprouts, it has been found effective to roll the seed in pine-tar, and then in plaster. The scent of the tar will remain a long time, and will be disagreeable to the vermin. The tar can be most easily applied by mixing it with hot water and then stirring in the corn.

Top-dressing Fall Grain.—Grainfields that look unthrifty and yellow after the drying winds of the spring, will be benefited by a top-dressing of active fertilizer; this will help the clover and young grass.

Plaster is often very useful upon young clover-fields—frequently doubling the hay crop. Thus applied, it will serve to produce a good crop to be plowed in upon distant fields where manure can not be easily handled. One bushel (80 pounds), up to four, six, or eight bushels even, may be used to the acre as early as practicable this month.

Early Potatoes, that have not yet been planted, should be got in without delay. With this crop earliness is a great advantage where beetles abound.

Pure Paris Green is the best remedy for the beetle. Last season we mixed it with plaster, which is much cheaper than flour, does not scatter so much when the wind is blowing, and adheres to the leaves equally well. As it is best to be prepared for the beetle, a supply of the Paris green should be procured in readiness for his arrival.

Root Crops.—The article upon "Root Crops for Stock," given last month, may be very profitably read over again. Nothing can be added to it, except, perhaps, to say that where the drill culture there described is found difficult, very good results may be had from culture on the flat. On the whole, mangels are to be preferred to any other root, as they yield better, are more certain, are less troubled with the fly, and make excellent feed.

Horses.—Now, with hard work, teams require good care. Horses will come from the field in much better condition if they are protected from worry by the flies. The best protection is a thin sheet made to fit the neck, with holes for the ears, and to buckle under the throat, and to cover the back, hanging loosely at the sides to give access of air beneath. It should be held by a crupper band beneath the tail. Too much corn fed now, is apt to produce irritation of the skin, and make the animals restless. Cleanliness will be found a great comfort to them.

Sheep and Lambs.—The most profit from a sheep is to raise a lamb that will sell for more than the mother is worth. This can be easily done by caring well for the earliest lambs. A lamb, 90 days old, and well fattened, will often sell for ten dollars in the cities, and half that in country villages. A half-bred Cotswold lamb, fed now with a little mixed oatmeal and bran, and suckled by a native ewe, will make an excellent market lamb. Lambs now being fed should be protected from cold storms, and the ewes should have some extra feed.

Sheep Washing.—To wash the wool on the sheep's back is not a profitable practice. The wool is not half washed, and the difference in price will not pay for the loss of weight, to say nothing of the trouble and risk for both men and flock. If the sheep are kept reasonably clean, and the wool free from rubbish, it will be found better than having to wash them to get rid of unnecessary filth.

Tagging the Ewes should not be neglected; the wool should also be clipped from about the udder. Much disease in the lambs is undoubtedly caused by filth in the mother's wool.

Plaster on Clover.—"J. G. W., Bates Co., Mo. Plaster should be sown upon clover as soon as the growth is vigorous in spring—about the first week in May is the usual time. 80 to 200 pounds per acre is used.

Cows and Calves.—Caution should be exercised in turning cattle on to the fresh grass. Young stock are especially subject to disease from over-feeding with succulent herbage. Black leg, black-quarter, or carbuncular erysipelas, frequent at this season, is so caused. Where there is danger, a seton in the dewlap has been found effective to prevent it. To change the feed gradually, however, is the best preservative of the health. In-coming cows that have been well fed should be watched to prevent garget. To reduce the feed before calving, and to guard the cows against lying out during cold rains, will be safe. Every owner of a cow should possess a good book on the care of cattle. Dadd's "Cattle Doctor" will be found useful in this way.

Swine.—Pigs given a run at grass will do best. The orchard, sown to clover, might well be appropriated to them in part. The effect will be beneficial in two ways; the pigs will have good grazing, and many vermin will be destroyed. If the pigs gnaw the bark, wash the lower part of the trees with some thin mud mixed with cow-dung. A feeding coop, such as is described elsewhere, is useful for young pigs. In this, some milk in a shallow pan may be given them without disturbance from older ones.

Poultry.—Young chicks should now be coming forward. As a rule, those hatched this month, if of good breeds, will begin to lay early in the fall, and continuing through the winter will brood early next spring. The profit of feeding laying hens, when eggs are scarce, is obvious. The loss in feeding "dead heads" through the winter, to lay only when eggs are plenty and cheap, is apparent.

Feed Little and Often to young chicks. Cracked wheat, swollen with hot water, and fed warm, and occasionally mixed with some of the animal meal prepared by Bowker & Co., of Boston, will push them on very fast. One heaped teaspoonful is sufficient at one meal for a brood of a dozen chicks. We find a good place for a coop is beneath a plum or cherry tree. A curculio has no chance to escape their sharp eyes. If properly cared for, poultry ought to pay more profit than anything else on the farm—the garden excepted, perhaps.

Fodder Crops for early use are to be put in as soon as possible. Make a succession of sowings, that the crops may follow each other every ten days.

Oats and Peas, sown together, give a large yield of nutritious green fodder. If the ground is rich and clean, $2\frac{1}{2}$ bushels of oats and $1\frac{1}{2}$ bushel of peas may be sown on a well harrowed field, and covered with a small, shovel-toothed cultivator. A broad, leafy oat and large-growing pea are the best. We have found the "Side" or "Horse-mane" oats and the "Black Marrowfat Pea," best for abundant fodder. For early cutting, the small "Gray Canada" pea, sown with barley, may be substituted.—*Tares or Vetches*, and the "Mammoth Clover" are good fodder crops.

The main Planting for fodder should be corn. The Evergreen Sweet corn; the early Canada Dutton, King Phillip and other small-growing varieties are best. Plant with the Albany, or other planter, in rows 30 in. apart and close together in the row, using about 3 bush. of seed per acre. A fine fertilizer, such as guano, or one of the special corn manures, may be dropped along with the seed with the planter mentioned. If barn-yard manure is to be used, the drills may be opened with a plow, the manure scattered in the furrow and covered with the plow and the seed planted with the planter, or be sown by hand on the manure and covered by the plow. A grain-drill with only three spouts open may be used for sowing fodder-corn.

Poultry Manure.—This is a valuable fertilizer, and may be used with most benefit on corn. It may be scattered in the hill at planting or afterwards spread about the hill upon the surface. It is well to mix it with an equal bulk of plaster.

Notes on Orchard and Garden Work.

It is a common saying among cultivators that, no matter whether the spring is early or late, vegetation will be found the first of June to be about the same, taking one year with another. Still, near New

York, as we look from the windows of our country sanctum on April 15th, we feel very sure that we never saw the grass on the lawn so dark a green and needing cutting so much; we have never seen the pear-trees so nearly in full bloom, or the flowering-shrubs so far advanced as now, at any previous writing of the May Notes. This unusual season has made it necessary for us to look further ahead in preparing these Notes, and our often repeated suggestion to consult those of the previous two months, is enjoined with especial emphasis.

Orchard and Nursery.

Planting is generally finished before this time. Trees that have been properly heeled-in will be sufficiently retarded to allow them to be sent from the nurseries. Trees in transit in warm weather are liable to injuries; the methods of treating these were given last month.

Grafting is one of the operations that had better be done too late than too early. The proper time is when the swelling of the buds shows vegetation to be active, and it is risky to do it earlier. The most successful grafting of an orchard we ever saw, was done while the trees were in full bloom. At this season the bark slips readily, and care is required in sawing off the limbs, not to strip it and make a bad wound. It is better now, to quite cut through the bark with a strong knife all round where the saw is to work. Grafting-wax for use now should have more rosin in it, to make it harder, than that applied in cooler weather.

Buds below the Graft.—A gentleman about to graft informed us that he was advised by "a professional," to "scrape the branches," in order to remove every bud below the graft, and called to inquire as to the propriety of this. Whenever a bud starts into growth, the sap flows towards that bud. The buds on the cion are dormant, and will remain so until a union is formed with the stock, sufficient for that to supply the cion with sap to allow its buds to commence growth. If the stock or its branch is entirely deprived of buds, the sap has little inducement to ascend, but if the buds are left nearly up to the point where the grafts are inserted, their starting will cause an abundant supply of nutriment to flow to them, and the chances of the success of the grafts greatly increased. When the buds on the cions have commenced to grow—and not until then—the young shoots below are to be broken or rubbed off.

Insects will increase as the supply of food becomes abundant. Eggs of the *Tent Caterpillar* that have escaped observation, will now hatch, and the small caterpillars will commence to feed, making their webs, or "tents" while yet small; these are best seen while the dew is on them, in early morning. Lye, whitewash, petroleum, and other things have been advised, to be applied with a swab. The quickest, easiest, and surest way is to remove the web, morning or evening, when all are at home, by the hand—gloved or not—and throw it upon the ground and stamp it. *Lovers* in the apple and quince are detected by their saw-dust, and by a depression in the smooth bark, those in the peach and other stone-fruits by an exudation of gum. They must be cut out, or be probed and punched to death by means of a wire. *Curculio*, on stone-fruits generally, but on the plum particularly, begins work as soon as the fruit is set; jarring the tree, catching the insects on a cloth, and then killing them, is the only remedy. *Plant Lice* often cover the young shoots; strong soap-suds or tobacco-water will kill them; on low trees the branches may be bent down and dipped; on others the liquid must be freely applied by a syringe or garden-pump.

Young Trees should have the soil kept clean and mellow among them, and, especially if set this spring, should have a mulch before dry weather sets in. A tree properly planted rarely needs stakes, but if any are disposed to grow crooked, it is best to remedy this while they are young, and stake them.

Thinning of Fruit.—Those who practice this, should begin as soon as the crop is fairly set. Others may doubt its value, but no one who grows choice fruit for market can afford to neglect it. The experience of a single season with two trees,

side by side, will decide the matter. Let one tree ripen all the fruit that sets, and from the other remove three-fourths of the crop. Keep an account of the cost of thinning, and of the returns from the fruit from each tree.

The Black Rot is not confined to plum trees, but attacks cherries, and we have seen the same or something very similar on Nectarines. At its worst it is in the form of large black, ragged excrescences; it begins by a small swelling and breaking away of the bark. Cutting off and burning all affected branches is the proper remedy. When the excrescences are not large and few, cutting them out down to sound wood, and washing the wound with a solution of chloride of lime has been found useful.

The Blight comes without warning; we only know of it by the death of a branch, several branches, or sometimes of the whole tree. Cutting back to sound wood, if it takes the whole tree, and burning the prunings, is all that can be done.

Seed Beds of fruit and forest trees should be kept free of weeds, the soil loosened, and where the seedlings stand too close, thin them. Forest-tree seedlings, especially evergreens, must have shelter from the hot sun; a lattice of laths, or a screen of brush may be put over them, but supported in such a manner as to allow a free circulation of air.

Fruit Garden.

Mulching is of great benefit to a large share of the small fruits. A mulch, while it prevents evaporation and overheating the soil, allows the rains to pass through, and by preventing the beating of storms, keeps the soil mellow and porous. Because those who live near the coast often write of the benefits from using salt hay, many have an idea that this is the necessary material for a mulch. Whatever mechanically protects the soil, and meets the above-named conditions, may be used. Bog-hay, straw (always abundant in grain districts), corn-stalks, chips (sawdust is not advisable, as it breeds fungi,) spent tan-bark, litter from stables, and even small stones, have all been successfully used for the purpose.

Insects will be troublesome here. See Notes on Orchard, for insects attacking trees. Those peculiar to special fruits are treated under the proper head.

Strawberries.—The sooner the mulch is applied, the better; aside from its other uses, it is important in keeping the fruit clean. In some States, the harvest is over; in others, it is now at its height, while it is still anticipated elsewhere. Too much care can not be given to picking and pickers. We saw (April 15) a fine lot of South Carolina berries with their value diminished one-half because an over-ripe berry or two was in each basket. The further the distance the fruit is to be sent, the less ripe it should be. For near markets, the fruit is best picked into the baskets, and not again handled; but if to be *en route* for 24 hours or more, it should be picked in flat baskets, taken to a shady place to cool off, and then carefully assorted and put into the baskets or cups, taking care to put in not a single berry so ripe that it will soften and crush on the passage. The precise degree of ripeness can only be learned by experience, but it is safe to say, in general terms, that for a trip of 24 hours, no *full-colored* fruit should be packed.

The White Grub often makes sad work with strawberries, and their presence is not known until the mischief is done. When a strawberry plant wilts, take it up and search for the grub before it gets to and eats the roots from another plant.

Blackberries and Raspberries will now be making their growth of canes for next year's fruiting. Three or four canes are usually enough for each stool, all others are to be cut away. As soon as tall enough, tie them to the stake or trellis, and when they reach the desired height, stop them by pinching out the top. Three to four feet is enough for raspberries, and six or seven for blackberries. If rust appears, cut and burn the diseased stems.

Currants and Gooseberries.—No plants are more benefited by a mulch than these; very littery manure is excellent for them; it tends to prevent mildew, and greatly prolongs their season. The cur-

rant-worms must be taken in hand at their first appearance; the insect deposits its eggs on the under side of the lower leaves, and if a watch is kept for these, much trouble may be avoided by crushing the eggs. As soon as the leaves appear to be eaten, begin the war. *White Hellebore* is the efficient remedy. It is sold at the drug stores in fine powder. This may be sifted upon the bushes, but it is better to apply it with water. Put a table-spoonful of the powder into a bowl or other vessel, and pour on a little boiling water; thoroughly stir until the powder is all wetted, then add more boiling water, a quart or so, stirring to completely mix it; pour this into a pail, filling the pail with cold water. Apply this with a syringe or garden pump; in three days apply again; if more worms appear, repeat. Three applications are usually sufficient.

Grape Vines, in northern localities, at least, do not need a mulch; they do better with their roots in warm soil. Sufficient is said on the management of the vine at this time on page 182. As the shoots develop, there will often be found a caterpillar enrolled in the young leaves. It does less injury than may be supposed, though as it disfigures some of the leaves, it is well to remove it, which can only be done by hand picking. When the vine flowers, Rose-bugs will usually find it out, and gather upon the clusters. Early in the morning, while they are torpid, shake them off into a pan or other vessel containing water, and kill afterwards by scalding. Beetles and other large insects that appear later, must be hand-picked.

Training the Vine.—If one has only a few vines, it will pay him to train them in a regular manner, if the situation will allow, and to have Fuller's "Grape Culturist," or other good work, as a guide. Our remarks on page 182 apply to young vines. For fruiting vines, we may state a few general principles, applicable to all vines, however trained. The fruit is always borne on the shoots (see page 182) of the present year. The clusters of flowers, and afterwards fruit, appear opposite the lower leaves in the place of *tendrils*. There are usually three of these, rarely more than four. Market growers find that it pays to remove all but one or two bunches. When the shoot has made two or three leaves beyond the uppermost cluster, its further growth may be stopped by pinching off the end, though some prefer to leave four or more leaves. *Lateral*s will appear on these shoots, which are to be treated as directed on page 182. All barren shoots, unless wanted to supply canes for next year, and all shoots that appear where they are not wanted, are to be broken out as soon as they start. The young shoots are very brittle, and should be kept tied up to the wires of the trellis, if the vine is trained to one.

Kitchen and Market Garden.

In many localities it is the custom to move on the first of May, and those who are so unfortunate as to change their residence at this time, will begin their gardening rather late. This should not discourage them, as, with the exception of a few things, late sowing will generally give good crops, especially if there is water at command. Those who begin late will find many useful hints in these Notes for the past three months, and if in doubt about varieties, they may consult the list on page 62 in February last.

Succession Crops of spinach, radishes, etc., should be sown every 10 or 15 days, to keep up a supply.

Tender Vegetables, such as squashes, melons, and all of that family, beans, okra, etc., are to be sown at corn-planting time, when the soil is warm.

Buying Plants.—Those who have small gardens and have not much time, will find it cheaper to buy the few tomato, pepper, egg-plants, celery, and such other plants as they need, than to raise them.

Asparagus should be cut by a careful hand, who will not injure the plants. That for market should be bunched and kept in an upright position.

Beans.—For runners, set the poles first, in well-manured hills, 4 feet apart each way. Limas should not be planted until cold rains are over; put into the ground eye downwards, 4 or 5 beans to the hill,

Beets.—Thin the early-sown; the thinnings make excellent greens and are preferred by many to all others; sow the main crop—Long Blood is best.

Carrots.—Sow, using a plenty of seed, so that the plants may break the ground well.

Cabbages and Cauliflowers.—Set out from hot-beds as soon as the plants are well hardened, setting well down in the soil. Sow seeds for the late crops.

Celery.—Sow seed, if not already done, covering but lightly; roll or pat the surface down firmly with the back of the spade. The soil must be worked as soon as the rows can be seen; to assist in this, sow a few radish-seeds with the celery.

Corn.—Sow early sorts as soon as safe, and it is well to put in a little, in advance of the season, to take its chances. The drills may be 3 or 4 feet apart, according to the height of the variety.

Cucumbers and Melons.—Sow seeds and put out plants from hot-bed as soon as cold nights are over. Hand-lights are useful for these.

Egg-Plants are the last thing to go from a hot-bed. Set when the weather is warm. Look out for potato-beetles, which are very fond of these.

Horse-Radish is usually put between rows of early cabbages. Plant the sets 10 inches deep.

Kohlrabi.—Sow, and thin plants to 8 or 10 inches.

Lettuce transplant from hot-bed; sow for late crop.

Squashes.—Make well-enriched bills for the bush-sorts, 4 feet each way, and manure the whole ground for the later kinds with well manured hills 8 feet each way, using an abundance of seed.

Sweet Potatoes.—Put down well decomposed manure in rows 30 or 36 inches apart; with a garden plow turn a furrow towards it from each side, to form a ridge; afterwards finish up the ridges with hoe and rake. Plant the potato sets or slips on this ridge, 15 inches apart; open a deep hole with a dibble or mason's trowel, and put the set down so that several joints will be covered. If the soil is not fresh and moist, pour water into the holes, and let it soak away before setting the plants. The last week in May, or the first week in June, is early enough for the climate of New York City.

Tomatoes.—A light, warm soil gives the earliest crops, but the bearing lasts longer in a strong and rich one. In a garden, a trellis, or some kind of support, should be given the vines. Our past volumes give a number of devices. Brush, to keep the fruit from the earth, is better than nothing.

Weeds and Weeders.—As soon as the rows of seedlings can be seen, break the crust; this is especially necessary in soils that bake on the surface. An excellent implement for this and much other weeding is a rake with long, sharp teeth; this used when weeds are very small, allows of rapid and effective work; the sun disposes of the uprooted weeds by thousands. Another implement that we can commend to every gardener is the lance-headed hoe. We are not aware that the best form is on sale; we have ours made. The blade is a triangle of steel $4\frac{1}{2}$ in. long by $2\frac{1}{2}$ in. wide at base, and flat; a saw-plate will answer. This is riveted to an iron rod shaped like a goose-neck, of such a bend as will allow the blade to lie flat when the handle is erect; the rod is fastened into a common hoe handle. If the edges are kept sharp, an astonishing amount of work may be done with it.

Odds and Ends.—Do not delay brushing peas until they fall over....Slaked lime, or a mixture of unleached wood ashes and plaster (gypsum), should be kept at hand; it is not only a good fertilizer, but of great use on young cabbages, turnips, young plants of the squash family, and all others attacked by the flea-beetle, and other small insects....Hand-pick the first crop of potato-beetles on early potatoes, and be ready to give Paris green when the larvæ appear....Have a supply of seedlings of Sage, Thyme, and other sweet herbs, to occupy the land when other crops come off....Thinning is rarely done to excess; the earlier it is done after the plants are large enough to handle, the better; root crops should be at least as far apart as the average diameter of the roots, and more would be better....All vegetables to be sold should be sent to market in neat order; beets and

all roots, asparagus, rhubarb, etc., are to be washed and put in bunches.

Flower Garden and Lawn.

If a lawn must be started so late as this, it is advisable to use turf, if it can be procured. See last month on sowing grass seeds; it is well now to mix a quart or so of oats with each bushel of grass seed, that the oats may shade the young grass; the oats should be mown before they flower.

The *Lawn Mower* should be used on well established lawns once a week or ten days, until the drouths come, when the slower growth will require it less frequently.

Weeds in Lawns, if annuals, are soon killed by frequent mowing; thistles, docks, plautains, and other perennials, can be pulled, when small, if the ground is moist, or if too large, cut below the surface with a knife. A few children will soon clear them out at a little expense.

Bedding is usually of greenhouse tender plants, which should not be put out until cool nights are over, and they should have rich soil, that they may produce an effect as soon as possible. Most annuals used for bedding are hardier, but these need shelter, if cold winds come before they get established, by brush stuck amongst them.

*Cannas and Tuberose*s ought not to be put out until settled warm weather, and where this comes late, it is well to start them in boxes of earth in a greenhouse, frame, or sunny window.

Gladioluses are almost hardy. It is well to make two or three plantings at intervals of two weeks, to prolong the blooming season.

Dahlias are very tender, and are best started in a hot-bed, or in a sunny corner where they can be sheltered at night. Before planting a Dahlia, plant a stake, and keep it tied up as soon as tall enough to tie, else a wind will break the tender stem.

Evergreens are, according to some, likely to do better if transplanted just as the new growth starts; our experience is, that the important point is to never let the roots get dry; an exposure of an hour to drying winds will often place the roots in a condition past recovery. We can not too highly recommend the practice of *mulching* newly-planted Evergreens with stones. Place stones from the size of a cocoanut up to as large as one can conveniently lift all around the tree and over the roots; these will keep the roots moist, and anchor the tree better than any stakes; these trees offer great resistance to the wind, and are often bent in the direction of the prevailing gales, unless some such precaution is taken.

Climbers should be introduced wherever there is a proper place for them. A rough screen covered with annuals, such as Morning Glories, Canary Creeper, Thunbergias, etc., and with Maderia Vine, Maurandia, Cobæa, etc., may be made to shut out an unsightly object and be pleasing in itself. Sweet Peas should have been put in as soon as the ground was open; if sown now, put two or three inches deep; if no other method is better, stick them like garden peas; have a plenty for cut flowers.

Annuals started under glass, or in window-boxes, should be hardened off by gradual exposure, before putting them in the open ground.

Perennials of the later kind may be had of the dealers. Do not forget Chrysanthemums to make the garden bright until the last.

Roses require almost as much care, so far as insects go, as potatoes; but these are as essential in the flower garden as the potatoes in the kitchen garden. Begin with tobacco water for the Rose-louse or aphid; go for the slug with White Hellebore, as advised under Fruit Garden, for Currant Worms. When the Rose-bugs come, treat them as directed under Grape Vines.

Greenhouse and Window Plants.

The custom of completely clearing out the greenhouse is not so general as formerly. With proper attention to shade, and water, and insects, it may be kept attractive all summer. If one has

provided Gloxinias, Gesneras, and other summer bloomers, a grand show may be made.

Evergreen Plants, such as Camellias, Ardisias, and other broad-leaved sorts, must have partial shade, but not under the drip of trees; must be set upon coal ashes, so that worms will not enter the pots; must be placed where they will not be blown over; and must also be put where they will not be neglected if they need water, or other attention.

Fuchsias and Cactuses, the summer bloomers, make grand ornaments to a veranda, and they can have the needed shade and care. The Caeti, when making their growth, need water, however dry they may be kept when at rest.

Plunging Pots of plants may often be done with advantage to decorate the grounds. Put the rim of the pot just level with the ground and place a layer of coal ashes under the bottom to keep out worms.

Hanging Baskets often used on verandas dry out very rapidly, especially those of wire-work lined with moss. Every few days these should be placed in a pail or tub of water and soaked thoroughly.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our daily record during the year, show at a glance the transactions for the month ending April 12th, 1878, and for the corresponding period last year:

Gold has been up to 101½, and down to 100¼, closing April 17, at 100¼, as against 100½ on March 12; 101½ on Feb. 12; 102½ on January 12; 103 on December 12; 102½ on Nov. 12; 103 on October 12; 105½ on July 12; 104½ on June 12; 107¼ on May 12; 105½ on April 12, of last year. An active business has been transacted in Breadstuffs, during the month, largely on export account, and in this connection, especially notable in Wheat, Corn, Rye, and Barley, with, toward the close, a considerable movement in No. 2 Chicago Oats for shipment to France. Prices of most articles in the Breadstuffs line, however, have fluctuated frequently, and widely, as influenced, mainly, by the tenor of the cable reports from Europe, as to the political position and outlook there. Speculation was stimulated early in the month by the warlike advices, but with the more peaceful aspect of the foreign situation, as represented later on, this feature measurably subsided. As we close this, the general market is irregular, and rather weak. The purchases of Rye for Germany and Holland reached unusual proportions. Provisions were quite freely dealt in, Hog products attracting most attention, largely on speculative account, but at very variable figures, leaving off, as a rule, heavily, under urgent offerings. Butter, Cheese, and Eggs receded in value, on liberal supplies and a moderate demand. Hops and Seeds were less sought after, and fell off materially. Wool was much depressed, and in comparatively limited demand, as well for manufacturing purposes as on trade account, closing in favor of buyers. Tobacco has been in less request, and quoted lower. Export movement light. Hay and Straw have been quite moderately dealt in, but, as a rule, quoted about steady. Ocean freights have been more active, but unsettled as to rates, leaving off weak. Grain rates by steam to Liverpool closed April 12th at 8d. (about 16 cents) per bushel; Glasgow, 8½d.; London, 8½d.; Bristol, 9d.; Hull, 8½d.; the Continent, 8½d. by rail to Liverpool, 6½d.; London, 7½d.; by steam to Liverpool, by steam, 2s. 9d. (about 66 cents

per bbl.); by rail at 2s. 3d.; London, 2s., and by steam, 3s.; Bristol, by steam, 3s., and sail, 1s. 10½d. per bbl. Provisions by steam to Liverpool, 30s. 35s. per ton. Cotton by rail 1½d. ¼d., and steam 7½d. ¼d. Grain, by rail, for Cork and orders, at 6s. 6d. 3d. per quarter, (8 bushels), and to Continental ports, 5s. 6d. 6s. 3d.; Italian ports, 5s. 6d. 6s.; and from Philadelphia for Cork and orders, 6s. 6d. 3d., and from Baltimore for Cork and orders, 6s. 6d. 6s. 9d., in bags, 15 15½ cts. per bushel.

Two Months More.

IMPORTANT.—The Publishers of the *American Agriculturist* employ no agents; the high cost of making the paper and its low subscription price do not admit of this. But they do offer something in the way of recognition, or remuneration, to friends who take the trouble to show the paper to those not acquainted with it, and receive and forward their subscriptions. This assists the Publishers, and is beneficial to those solicited to subscribe. The remuneration is given in the form of **highly useful and always valuable** articles, which are named and described in a Premium List, a copy of which is supplied to every one desiring it and not having it.—The articles offered are *first-class, and just as good as money*, though by special arrangements, and large wholesale cash purchases, they cost the Publishers less.

The list of Premiums is open to all until July 1st, when it will be **positively withdrawn**. There are therefore just **2 months more** in which those who have begun lists may fill them out. **New Lists** may be begun by **any one**. Those who have struck for a larger premium, and have not succeeded in getting that, may select a smaller article, and complete their list to get that one. There is

Plenty of Time Yet to fill out lists in progress, and to begin new lists, and complete them during May and June. (A lady begun the second week in May and procured subscribers enough within one month to secure free a \$650 Steinway Piano.—A farmer in three weeks secured a Buckeye Mower free in the same way, without neglecting his work; and many others have in like manner got large and valuable premiums in a short time in May and June.) There is a large list of good articles to select from, varying all the way from \$1 to \$650 in value, **given free**, for from 3 subscribers upwards.

Over **20,000 persons** have received these valuable premium articles **free of cost**. Reader, Try it this month. A little effort now will secure you one or more valuable articles the present season.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

Publishers' Notices, Terms, etc.—The Annual Subscription Rates of the *American Agriculturist*, postage prepaid by the Publishers, are: One Copy, \$1.60 a year; Two Copies, \$3; Three Copies, \$4.20 (\$1.40 each); Four Copies, \$5.30 (\$1.30 each); Five to Nine Copies, \$1.25 each; Ten to Nineteen Copies, \$1.20 each; Twenty Copies and upwards, \$1.10 each; Single Numbers, 15 cents, post-paid.—The above terms are for the United States and Territories, and British America. To the above add 14 cents extra per year for papers delivered by mail in N. Y. City, and for copies sent outside of the United States and British America, except to Africa, Brazil, British Honduras, the East Indies, and Mexico. For the last named five countries the extra charge is 38 cents per year, to cover extra postage; Single Numbers, 17 cents, post-paid. **Remittances**, payable to Order of Orange Judd Company, may be sent in form of Checks or Drafts on N. Y. City Banks or Bankers; or P. O. Money Orders; or in Registered Letters, such letters to have the money enclosed in the presence of the Postmaster, and his receipt taken for it, and the postage and registering to be put on in stamps. Money remitted in any one of the above three methods is safe against loss. **Bound Volumes** from Vol. 16 to 36 inclusive, supplied at \$2 each, or \$2.50 if to be sent by mail. Sets of numbers sent to the office will be bound in our regular style for 75 cents (30 cents extra if to be returned by mail). Missing numbers for such volumes supplied at 12 cents each.—**Any Numbers** of the paper issued for 21 years past, sent post paid for 15 cents each; or any full year, sent unbound, for \$1.60. **Clubs** of Subscribers can be increased at any time, at the club rates, if new members begin at same date as original club.

Every German Cultivator and Laborer on the Farm, or in the Garden, OUGHT to have the German *American Agriculturist*, and thousands of new subscribers are taking it this year. It contains not only the Engravings and all the essential reading matter of the American edition, but an additional *Special German Department*, edited by the Hon. Frederick Münch, of Missouri, a skillful and successful cultivator

and excellent writer. No other German Agricultural or Horticultural Journal in America has been so long issued; no other contains so much useful information and so many engravings. Germans are a *reading, thinking* people, and know how to make good use of what they read. Many Americans supply it to their German laborers and gardeners; all would find it pay to do so.—*Nothing else can compete with it in cheapness of price for the same amount of material, engravings, etc.*, because the expense of collecting and making these is largely borne by the American edition, and no separate office or machinery is required beyond German editors and the printers. Its terms are the same as the American edition, singly and in clubs; and clubs can be composed of subscribers for either edition in whole, or in part.—*Please call the attention of your German neighbors to this paper.* It will do much to help new comers to a knowledge of the system and modes of culture used in this country.

A Microscope for Every Subscriber.—Every subscriber to the *American Agriculturist* for 1878, is entitled to receive one of the *American Agriculturist* Microscopes, delivered free anywhere in the United States or Territories, on remitting 60 cents; or for 40 cents if the Microscope be taken at the office (Our arrangement for delivering them by Express at reduced rates has expired). The invariable price to non-subscribers is \$1.50, or \$1.65 if sent pre-paid. Even without the paper, it is, at \$1.65, far cheaper than any microscope of equal usefulness that was ever before offered. By new methods, and by making them on a scale twenty times greater than ever before attempted, the cost has been greatly reduced. These special advantages are reserved exclusively for the subscribers of this Journal for the present year; and by paying part of the cost themselves, the Publishers supply them at the nominal price above named.

Hundreds of Letters have been received since sending our April number to press, from Subscribers, expressing great satisfaction and pleasure in the use of the *American Agriculturist* Microscope. It could not be otherwise with any person who is acquainted with such instruments, or who, not being acquainted with them, will take a little pains to get familiar with the proper use of this one. To such it opens almost a new world of objects, and is a source of instruction as well as amusement, especially to the young. Although its continued distribution is a source of loss, we shall, for the present, continue the offer of these Microscopes, as hitherto, except the addition of 5 cents to the cost of delivery above named.—After our subscribers are supplied, they will probably be put into the regular trade at \$1.50 each, which is far cheaper than any microscope of like value and usefulness has ever before been offered.

Life Insurance.—Our views of the importance of this were given in March, page 86. The statement of another of the old substantial first-class companies will be found on page 200 of this paper. The figures speak for themselves. The terms, tables, etc., can be obtained without charge, from Mr. L. S. Goble, 137 Broadway, N. Y.

To Officers of State and County Fairs.—As the time is at hand when arrangements are to be made, and Premium Lists prepared for State, County, and other Agricultural, Horticultural, and Industrial Fairs, we would remind those who make up the schedules and prizes, that no more acceptable Premiums can be offered than some of the very useful and valuable Books for the Farm, Garden, and Household, or a year's subscription to the *American Agriculturist*. We invite correspondence from those who have these matters in charge. Premiums like those we suggest, have been offered in many cases, to the great satisfaction and benefit of those who secure them, and who place a greater value upon such permanent, useful keepsakes, than they would upon several times their cost in a money premium.

Crandall's "Chinese Blocks."—All children will remember Mr. C. M. Crandall with gratitude, as the man who has given them the means of unbounded delight. And now he comes again with a new "Block," combining the original Building Blocks with a Chinese Family, the various pieces being beautifully colored, and a single Set enabling its fortunate owner to build, without number, Chinese Houses, Palaces, Pagodas, etc., etc. See Third Cover Page.

Cuba, and "Crandall's Heavy Artillery."—An American, who has resided for some years in Cuba, last fall visited his father, who lives in this country. When he returned some weeks later, he took with him a set of "Crandall's Heavy Artillery,"—a most fascinating toy of its kind, which is to be found in toy stores almost everywhere. When his baggage was examined by the Custom House officials in Cuba, this innocent, though formidable looking affair was found, and the sharp-eyed officials, concluding it was some new engine of destruction, designed for the use of the insur-

gents, threw its owner into prison. His confinement, which lasted seven weeks, brought on a fever, and he lost his hair in consequence. The U. S. Consul at last procured his release, and one of the too hasty Custom House men was discharged. Our unfortunate American, however, soon learned that a plot had been laid to assassinate him, and he fled the country, being now safe at home.—*Moral.*—Everybody should buy this remarkable and interesting toy, which can be had for \$3.00 at this office. Expressage to be paid by recipient.

Reliable Business Men, those who have both the *ability* and the *intention* to do what they promise, are the only ones invited to use the business-pages of this journal, and those in charge of that department are under positive instructions to admit no others at any price, and they try to live up to it, and generally do, though once in a while they may make a mistake—to err is human—but *this* seldom occurs. We could make a fortune in a single year, and supply the paper at lower rates, if the advertising pages were thrown open to those who gladly pay high prices, as they can afford to, because they give little for much. But we mean our advertising pages shall be a valuable source of *trustworthy* information to our readers.—When ordering from, or corresponding with any of our advertisers, or sending for catalogues, etc., it is well to state that you are a reader of this Journal. They will know what we expect, and what you expect of them as to prompt and fair treatment.

The Death of Clarkson Taber is announced as having occurred at his farm in Sterling, Kansas. The account is very meagre, and the date is not given, but we suppose it took place about the middle of April. Mr. Taber was born at Albion, Me., in 1822, and was educated at the Friends' School, at Providence, R. I. In his early life he was engaged in the nursery business, and he had an excellent knowledge of that branch of horticulture. He became connected with the *American Agriculturist* in those primitive days when one person could do all the mailing, attend to the advertising, besides making himself generally useful; later, he made up the cattle reports, and afterwards performed similar duties for the "N. Y. Tribune." Mr. Taber was a faithful, industrious worker; he was a consistent member of the Society of Friends, and was highly esteemed by all who knew him. To his old associates this unexpected news of his death brings sincere regret, but awakens none except pleasant remembrances of a genial intercourse of many years.

Coloring Butter.—As long as the demand exists for high-colored butter, and consumers will pay an extra price for it, so long dairymen will color their product. Some people love to believe that Jersey cows *always* yield very yellow butter. Ordinarily they do, but sometimes even the best Jersey butter is colored artificially. If butter is to be colored, it were well that it were well done; and it cannot be well done without a good coloring preparation. We have tried several preparations, for when our butter in the winter season lacks color, we do not hesitate to please our own taste as well as those to whom we sell, by giving it the right tinge artificially. Of the colorings we have used we prefer two; that prepared with oil, by Mrs. B. Smith, Philadelphia, and that of Wells, Richardson and Co., of Burlington, Vt., which is a popular liquid coloring prepared in a different manner. There probably are others as good perhaps, but these are good enough to produce a lemon or a golden yellow as may be desired.

Don't Pull out Loose Teeth.—As soon as a tooth appears a little loosened, there is always an itching, among young people especially, to get the thing out. While artificial teeth are made very perfect, and are exceedingly useful, any natural tooth that is not damaged so as to ache incurably, is worth a score of the best artificial dentures ever made, and great care should be taken to keep it in as long as possible. Some months ago the writer had two front teeth so loose that they could be readily moved back and forward more than their diameter, by a slight pressure with the finger. But by a little care not to use them on hard substances for a few days, and keeping them pressed into place with the teeth opposite, they settled back into their natural position, and are now serviceable, thus saving two ugly gaps, or the expense and annoyance of artificial ones, and the annoying mouth-plates. Recent experiments by Dr. Kingsley and others show that the teeth may be "moved along," may be made to change their position very greatly, so as to get a regular set of natural teeth out of one previously more irregular than a Virginia fence. In a case under our own observation, the upper jaw was full of teeth, and had two extra ones that grew in front of two others—real "tusks." Yet the dentist spread the roof of the mouth by ingenious plates, screws, etc., and actually moved the other teeth along, bringing the extra fellows into line, and now there is a regular row of useful

teeth, where formerly it seemed as if the young man (now in College) had got to wear through life a very uncouth, distorted set of dentals.

Books Upon Poultry Raising.—

"W. G. L.," Ford Co., Ill. A very useful and cheap book upon poultry raising is "An Egg Farm, etc.," by H. H. Stoddard, who is a practical poultry breeder. It contains selections and illustrations from the back volumes of the *American Agriculturist* from articles written by Mr. Stoddard and those editors of the *American Agriculturist*, who have been largely and successfully engaged in raising poultry. It must not be expected that any book whatever can provide for every contingency and accident; judgment and common sense must be used when the directions given do not precisely meet any particular case. Only general rules can be given in books. Sent by mail in paper covers, 50c.; in cloth, 75c.

A Business Change.—

Mr. W. Atlee Burpee has retired from the firm of Benson, Burpee & Co., 223 Church Street, Phila., dealers in seeds, grains, and live-stock. The business will be continued at same location, under the firm name of Benson, Manle & Co. W. Atlee Burpee & Co. will conduct a similar business at 221 Church Street, Phila. Mr. B. is an enterprising, intelligent business man, and deserves success.

A Hay Fork Carriage.—"H. D. M."

The first necessity for the return of a MSS. is to send your post-office address. When a letter is dated only, and no place given, it is a clear impossibility to communicate by mail, although a stamp may be enclosed. Some people are very thoughtless in this regard, and blame us for what we can not possibly help. The drawing is received, and is only waiting for an opportunity to be published. It is not always possible to print any article the day or even month after it is received.

"Forestry and Its Needs," is the

title of an address, delivered before the "American Forestry Association," at the meeting held at Washington in February last, by its President, Doct. John A. Warder. It is brief but comprehensive, and shows that much careful thought has been given to the needs of our "forestry,"—if we can be said to have any in the proper sense of the term. We read to the very next to the last page, giving assent as we went along—feeling that here is a forestry movement which is not pivoted upon, and does not revolve upon the central idea, that the Government must send some one to Europe to examine and report—but, alas, here was the same old story, somebody must go to Europe. The suggestion that immediately precedes this is an admirable one, and would accomplish much good, viz., to introduce some of the many educated and trained foresters so numerous abroad, to teach in our scientific schools.

The Trial of Steam Engines for

farm uses, held at Syracuse last fall, under the direction of the N. Y. State Agricultural Society, was a very thorough one. Among the premiums then awarded was one of a gold medal to B. W. Payne & Sons, Corning, N. Y., for the best engine in the Second Class, *i. e.*, under 6-horse power. All the vertical engines made at their establishment are provided with "Taber's Patent Automatic Cut-off Governor," which, it is claimed, allows of the best control over the movements of the engine.

Sewing Machines.—

Over 20 years ago the *American Agriculturist* published the first popular description of "HOW SEWING IS DONE BY MACHINERY," showing by a variety of illustrative engravings just how the stitches were made by the leading machines, and setting the matter forth so plainly that ordinary persons could understand the whole process. This was in February, 1858. We have, from the first, recognized the importance of this labor-saving implement, and not only labor saving, but life and health-saving; and have many times urged every man to spare his companion the everlasting "Stitch, stitch, stitch! Sewing at once with a double thread, A shroud as well as a shirt," and advised selling an acre of land, if necessary, to secure this important aid in the household. Of course we have watched the progress of improvement, and have tried a majority of the machines brought out. So much by way of introduction to what we have to say of the New "Automatic" Machine of the WILLCOX & GIBBS COMPANY. One of these has been in use at home during three months past, by the same hands that have tested so many of the machines, from time to time spoken of in this Journal. It may be said in brief, that, all things considered, this is "The Best" one yet tried. Its elastic seam, easily fastened, and yet capable of removal when desired, is an excellent feature. It has sundry attachments, that work admirably, as the Hemmer, Tucker, Quilter, Ruffer, Braider, etc. It runs with wonderful ease and quietness. But the great improvement is the new "Automatic Tension,"

which is perfection itself. With this, the most inexperienced can sew the thinnest fabric as well as the thickest; and what is more, pass from one thickness directly to another, as often as desired, without changing the tension, and with the certainty of producing perfect work. Every lady who has used any machine and worried, and even cried, over getting the tension always right, will at once recognize the importance and value of such an improvement in sewing mechanism.

Relating to Shepherding.—"D. H.,"

Chicago, Ill. Stewart's "American Shepherd's Manual," gives full instruction for earing for sheep; all that is necessary in addition to what is there told, is some ordinary common sense, to apply it to differing circumstances. Kansas and Nebraska are good localities for keeping sheep. There a homestead can be bought cheaply, or taken on Government land for next to nothing, and for the present plenty of free pasturage can be procured. Probably the best plan would be to purchase 640 acres of cheap land from one of the railroads, and enter 160 acres of Government land, at \$1.50 per acre, adjoining it. This would give 800 acres, which would furnish winter feeding for three or four thousand sheep, and summer pasture could be had on the range. Either native or half-bred sheep could be purchased in Colorado at \$2 to \$2.50 per head. There is no necessity to purchase more land at present than sufficient for winter pasture, as plenty of wild hay can be put up for one or two dollars a ton. Price, sent by mail from this office, \$1.50.

German Millet.—"E. J. S.,"

Queenstown, Md. Millet can not be sown safely until the soil is warm. It thrives in warm weather. May and June are the months for sowing it. One to two pecks per acre will be sufficient seed.

Bean Planter.—"H. C. P.,"

Kinston, N. C. The Albany Corn Planter, made by R. H. Aden & Co., and illustrated in the *American Agriculturist*, April, 1877, plants beans as well as corn, and other seed. Any threshing machine will thresh beans, by putting a smooth plank in place of the concave, and running slowly.

Nebraska.—

Mr. Leavitt Burnham, the new Land Commissioner of the Union Pacific Railroad Company, has for many years been a resident of Nebraska. He is familiar with the country, and those who contemplate moving westward would do well to consult him. We learn that there is an unprecedented emigration this spring to that portion of Nebraska through which the Union Pacific road runs.

Capons.—"N. F.,"

Pieton Co., N. S.—A capon is an emasculated male of the ordinary fowl. The operation has the effect of greatly increasing the size of the bird and the tenderness and flavor of its flesh. It is very easily performed when one knows how. The instruments are kept for sale by H. H. Stoddard, of Hartford, Conn., who can also furnish directions for operating. It is one of those cases in which seeing the operation is of greater value than all the directions that can be printed.

"Economic Tree Planting" is the

title of a pamphlet by B. G. Northrup, LL. D., Superintendent of Public Schools in Connecticut. Dr. Northrup is an enthusiastic advocate of village improvement, and has done much to organize "Village Improvement Associations," the good done by one of which, that of Litchfield, was described in Feb. last. The present work is a report to the State Board of Agriculture of his observations in Europe, on the economical aspect of tree planting, with added evidence of examples in this country. The work reaches us just at the moment of going to press, and we can at this time only briefly announce it. It will be supplied by the publishers of this Journal, and by mail for 25 cents.

Malt for Feed.—"J. A. McD.,"

Kiugs Co., P. E. I. Malt is eagerly eaten by all kinds of live stock, on account of its sweetness; but the result of many careful experiments has shown that the benefits derived from feeding it do not repay the trouble and cost in malting the grain. Every advantage from the malting may be gained by simply adding a little molasses to the fodder or grain, and this is much cheaper. In malting grain, there is a loss of substance, as well as a change of its form in germination, and this reduces the actual value of the grain, although it renders it more palatable.

Butter Table.—"H. K.,"

Blair Co., Pa. The butter table illustrated in March is not made for sale; any carpenter can make it from the description given. The moulds can also be made by any good mechanic. Most of the articles described and illustrated in the *Am. Agriculturist* are designed purposely for it, are unpatented, and are so simple and exactly described as to be easily made by any one who can use tools.

Sundry Humbugs.

We have often referred to the "Butter Compound," and the difficulty of getting direct information concerning it. This we consider one of the most pernicious of the swindles of the present day, as it is a fraud upon those who may use it, ignorantly and in good faith, and a fraud upon those who purchase, as butter, the stuff produced by its use. In view of its importance, we give in a separate article the results obtained by the Trustees of the "Mass. Society for the Improvement of Agriculture," and presume that they will in due time furnish the public the details in full.....Last

month, we gave a considerable space to an account of the operations of a firm calling itself

"CLARK & CO., ADJUSTERS OF CLAIMS, ETC.,"

who pretended to have money to the credit of various parties, and who, to be sure that they were addressing the right parties, enclosed a slip containing a signature for identification. One would suppose, from the account there given, that the scheme had been completely squelched. But these things have as many heads as Hydra, and as many names as a confidence-man, and while as "Clark & Co., 1,267 Broadway" that head is cut off, it already appears in another form. Precisely such letters as the one quoted last month, from Clark & Co.,—word for word—are being sent out right and left, but they are headed and signed, instead of "Clark & Co.," "J. C. Keys & Co.," and no longer from 1,267 Broadway, but are dated at "37 Bond St." Now 37 Bond street is the place where not long ago the celebrated firm of Russell & Co. were supposed to deliver those magnificent prizes of watches and jewelry from that "Decision at Last" Lottery Combination. Can it be that Russell & Co. have retired, or can one small number—37—hold two such firms as J. C. Keys & Co. and Russell & Co. at once? This last move more than confirms the opinion of that shrewd officer, Special Agent Sherrett, as quoted last month, that the Silver Mining Co., so flourishing last year, Russell & Co., and Clark & Co., were all schemes of Elias; evidently, Keys & Co. is but another alias of Elias. By the way, Keys & Co. do their business thoroughly, as we have two letters of the same date and exactly alike sent to the same person! Of course, when Keys & Co. are denied the use of the mails, as were Clark & Co., the check will be but temporary; as soon as some other name can be engraved on the letter-heads, the same thing will turn up in another form. Fortunately it is a scheme which will catch only those who are dishonest themselves....Circulars concerning a

WONDERFUL GOLD MINE,

are being circulated freely. They are sent far and near with an introductory note to the recipient which reads:

"Dear Sir—Returning from the mines, we met a gentleman in the cars from your locality, and asked him to give us the names of persons who might take an interest in mining. Therefore we send a prospectus, etc."

It is really astonishing how many people "we" met in the cars. The whole thing is "too thin"....We still receive inquiries concerning those parties whose circulars offer great inducements to invest in

STOCK OPERATIONS IN WALL STREET.

In all the many cases we have inquired into, the parties sending out these circulars are not members of the Stock Board, and they are not known at all, or are unfavorably known, among the regular dealers on the street. Our advice to every one who does not understand the business, is to keep out of the stock-market, whether in person or by proxy....There seems to be

A NEW CROP OF LOTTERIES,

at least, new in name, and we are often inquired of concerning them. We have very frequently given our opinion of lotteries, but as many new subscribers have been added since we have said anything about them, we state, in brief, that we are opposed to the whole of them, as wrong in principle and injurious to the community. Very few are honestly conducted, and if any are so, the chances are fearfully against the ticket holder. In most States the sale of lottery tickets is prohibited by law, and if, as they often are, tickets are sold in defiance of law, the purchaser is accessory to an illegal act. Never mind where the lottery is held, by what name it is called, or who give it countenance—let it alone....Every now and then the old story turns up in one form or another, that a farmer finds he has a note to pay

world, comes very near it; Mr. R. S. Emory, of Chester-town, Md., who would be a great peach grower he not a greater pear grower; Mr. T. W. Skirven, also of Maryland, and others from that State, with several from Delaware, including Mr. R. M. Cooper, a large grower in southern Delaware. Besides this, Mr. Peters has personally visited and made careful examination in many of the large orchards, and is better able to form an accurate opinion thereon, than, probably, any other person. The cold snap, to which the wide destruction is attributed, occurred on March 27th, when the mercury went down to 16°. At this time the trees in many parts of the peninsula were coming into bloom very freely; fortunately it was then and had been for nearly two weeks, exceedingly dry, a condition which Mr. P. thinks very favorable for the trees. He finds that in many localities, especially in the lower Eastern Shore of Maryland, and southern part of Delaware, the finer varieties of yellow peaches, such as Crawford's Early and Late, Reeves' Favorite, Susquehanna, and others, are badly damaged, while the white-fleshed varieties are but little injured. In the more northern localities the damage is not extensive. The foregoing is condensed from Mr. Peters' very full report, in which he sums up his own observations and the information he has received from others, by saying: "The prospect now is that we shall have more peaches than can be profitably shipped—provided, of course, that nothing happens to them after this date." The crops of all other fruits, including the small fruits, promise to be unusually fine.

Basket Items continued on page 193.

Between New Zealand and New York.

A large share of our correspondents in this country request us "not to give their names" in the replies in "Our Basket." Such a request seems strange, coming from New Zealand, yet there is quite as much reason for it, if not more, as in some districts at home. It implies that the *American Agriculturist* is so generally read in the writer's neighborhood, that every one will know that he has written. Many try all possible methods to get their names in print, while the majority prefer not to see it; then persons do not like to have their neighbors know that they have written anywhere for information, especially to a paper. The fact is, this paper has so large a circulation in the British Colonies generally, that it would astonish the reader should we give the figures, while the numbers, and their constant and rapid increase in New Zealand and Australia, are a wonder to the publishers, who are generally not astonished at anything in the way of circulation. We have our own notions as to the reason for our large circulation in these colonies, obtained without effort, and increasing by its own momentum; but we will not give them now. Suffice it to say that we are exceedingly glad to find a welcome among the wide-awake enterprising farmers and others in those colonies—for they were not settled by those who could not stay at home, and we read with no little satisfaction, in a recent letter, that there was not a farm-house in a certain district, naming it, and giving its extent, at which the *American Agriculturist* was not taken. In view of all this, we have been surprised that so few questions came from those colonies; with the exception of some, which, from their nature, required a reply by letter, they have been surprisingly few. We are glad of our present correspondent's, "L. W.'s," letter, as, besides allowing us to be of use to other New Zealanders in our reply, it permits us to say to him and others there, and in the other colonies, that he has not "taken too much liberty in addressing this note to you" (us), and that we welcome him and all others with their questions, assuring them that they will be treated "on the terms of the most favored nations," including that called the "Universal Yankee." We do not promise to answer every one—that is simply impossible—for we are often asked to answer the unanswerable—but we will so far as we can, so soon as we can, reply, if we can. We are glad to see that our friend asks for a reply in "Our Basket," as that shows him to feel at home in "the family," and accept that friendly relation which we desire to encourage. With this, for us, unusually long preface, but as it will have to be shared by thousands besides himself, will not leave him so very much, we will to the business of his note. He asks 1st. "By what means are small sums of money sent—i. e., sums less than £1 sterling—between New Zealand and New York?"...2d. "What is book postage from New York to this colony?"...3d. "Is there any duty on agricultural machinery made in the U. S., leaving New York to come to New Zealand, and if so, how much?"...4th. "I have applied to shipping agents to learn the R. R. freight of goods from New York to San Francisco, but can get no information."—Answers.—1st. Money Order on London, or Draft... 2nd. 4c. for 4 oz. or fractional part; if 4½ to 8 ounces, 8 cts....3rd. No duty on Agricultural machinery,

simply a clearance fee through the Custom House.... 4th. \$2.50 to \$3.00 per 100 lbs. on agricultural implements, the rates changing nearly every month.

Diphtheria and Filth.

Not long ago there occurred at Newport, R. I., the deaths of six persons in a family of eight, within fifteen days, all dying of malignant diphtheria. So remarkable an invasion of a dangerous disease naturally aroused the attention of the authorities, and the Mayor of Newport, properly employed Col. Geo. E. Waring, Jr., as Sanitary Engineer, to examine and report upon the condition of the premises. From this report we learn that the cottage is healthfully situated, with a cellar under all of the main portion, but there is a small addition, one story high, outside of the main foundation; this is used as a rear entrance, and contains a sink and a water-closet; and is only separated from the rest of the house by a thin board partition. The sink, in frequent use, had an imperfect trap, and this and the water-closet emptied into a cesspool which had not been cleaned out for several years. All of this was had enough, but this addition, or scullery, was raised upon brick piers, about two feet above the surface of the ground, with the space beneath closely boarded. In this space was the leaden pipe from the water closet, connecting with an earthenware pipe leading to the cesspool. Sea-weed had been at some time used around these pipes to keep them from freezing. The examination showed that, through some cause, whether by frost, corrosion, or the gnawing of rats, the lower bend of the leaden pipe, leading from the water-closet, and which was intended to serve as a trap, had broken through, and the deposits of the water-closet, instead of being carried off, in good part oozed through the hole in the pipe, and spread themselves over the soil and sea-weed, under this addition, for the extent of a square yard or more. How this state of affairs could have existed and not aroused attention, it is not necessary to discuss.—This is what was found; six children are dead, and it is no stretch of the probabilities to connect the one with the other. It is not offensive matter of this kind alone that is to be found near houses, in both city and country. Many a house with a fine front yard has a faulty kitchen drain. Nor is diphtheria the only disease that is favored by such conditions: typhoid and other fevers may be directly traced to the want of proper care in carrying off the wastes of the house—too often country-bonuses. The case of this Newport family is a distressing one, but if it will arouse a general attention, all over the country, to this matter of house draining, and this shall lead to remedying all defects in the disposal of the waste materials, the calamity will not have been in vain.

Bee Notes for May.

BY L. C. ROOT, MOHAWK, N. Y.

As the spring promises to be unusually early, in this latitude, at least, bees will undoubtedly be placed upon their summer stands during April.

The work for the present month is to secure as rapid breeding as possible, that all swarms may become populous. Be sure that each swarm has a good laying queen. With the movable comb-hive, this may be readily ascertained by lifting out a frame, when, if eggs are found in the cells, it is satisfactory proof that the swarm has a queen. With the ordinary box-hive it is more difficult to make this examination, yet with the use of the smoker, it may usually be done. Turn the hive you desire to examine, bottom up. Spread the combs a little apart at the

Fig. 1.—SMOKER.

center of the hive, and direct the smoke from the smoker to the exact point you desire to examine, thus clearing it of bees. If cells of sealed brood can be seen, it indicates that the queen is present. If sufficient honey is not gathered to continue breeding, sugar, syrup, or diluted honey, should be furnished for the purpose. If weak or queenless swarms are found, they should be united. Often two weak swarms may be united, making one good one, when both would be lost, if left separate. In uniting swarms, the smoker should be used freely, that all bees may become thoroughly demoralized. If sufficient smoke is used, there is usually little danger of their stinging each other.

Smokers.

The importance of some efficient mode of applying smoke in handling bees, is admitted by all practical beekeepers; while the Quinby Smoker, which has been described in these columns, has proved successful, there were some deficiencies in it, which experience has

remedied. During the past winter it has been much improved, so that it operates most perfectly. Figure 1 gives an accurate idea of what we call the *New Quinby Smoker*.

Section Boxes.

In Notes for March, 1877, I described a desirable form of the two-comb honey-box. The most popular box at

Fig. 2.—BOX.

present, in most markets, is a single-comb, or section-box. The one I use is made of white bass-wood, as follows:—Cut two pieces 5¼-in. long, 2 in. wide, and ½-in. thick, and two pieces 5 in. long, 1½ in. wide, and ¼-in. thick. Nail them together, as shown in figure 2, with ¾-in. cigar-box nails. This makes a box 5¼ in. square outside. The two wide pieces project over the narrower ones ½-in. on each side, giving room for the glass to rest on the narrow pieces. They should not be glazed until after they are filled. It will be seen that, by placing two or more boxes together, that there will be an opening ¼-in. wide between the boxes, where the bees may enter. A temporary separator, made of tin, or thin wood, should be placed between the boxes while they are being filled, to secure straight combs. A space ¾-in. wide should be left at the top and bottom of the separator to allow the bees to pass from one box to another, or they may be cut ½-in. smaller, on all sides, and attached to the sides

Fig. 3.—BOX.

Fig. 4.—BOXES IN CLAMP.

of the box, by narrow strips of tin, as shown in figure 3. The boxes may be arranged in a clamp, as shown in figure 4, if used on the top of the frames, and if placed at the sides of the combs, they may be arranged in frames, as indicated in figure 5. The separators should be on the side of the box next the combs, and the other side closed

Fig. 5.—BOXES IN FRAME.

with a close-fitting division-board, or glass. Each box should contain a guide-comb, as shown in figure 2. This should be fastened in with white glue.

Weight of Bees.

No. 1 consumed during March, 1 lb.; No. 2. 2¼ lbs.; No. 3. 3¼ lbs.; No. 4, which was out-of-doors, had been robbing, and had not lost any in weight.

A Small Street Swindle.—The "Alligator Plant."—Those traversing the New York streets during April, saw at the corners of the streets, near the ferries, and at other central places, overgrown boys and men, each with a pile of rough-looking sticks, calling on, "Here they are; a few more left. The genuine *Alligator Plant* from Florida. You have only to put it in water, and in a week it will be covered with beautiful flowers like roses. Only a few left! Who takes the next at 25 cents." (the price later was 10c., 5c., or less.) These sticks or twigs, one to three feet long, were uncouth enough in appearance to have come from the alligator swamps of Florida, but they only came from the nearby swamps of New Jersey. They were the small branches of the common "Liquidambar," or "Sweet

Gum" (*Liquidambar styraciflua*), common enough in New Jersey, and still to be found in the few remaining pieces of woods in the upper part of the city itself. It is a peculiarity of this tree that its young branches bear corky wings, often as broad as the diameter of the stem itself. The engraving, much reduced in size, shows the appearance of a bit of one of these "Alligator Plants." Many cart-loads of them have been sold in the city, and a large lot had been sent to Philadelphia. The sale began at 25 cents each, but the market closed lower, "in favor of purchasers," as the reporters have it. That large quantities have been sold, is shown by seeing the branches placed in water in the windows of restaurants, barber's shops, and such places, as well as by the number of people one meets carefully carrying their "Alligator Plants" home. To those who do not

TWIG OF THE SO-CALLED "ALLIGATOR PLANT."

know the tree we may say that, as to habit and foliage, which is star-shaped, it is one of the most beautiful of our native forest trees, but the flowers are no more like roses than are those of the Button-ball. They are very inconspicuous, the staminate or sterile flowers in little conical clusters, the pistillate in small globular heads; they have no petals or showy parts, and one unfamiliar with such matters, might not even notice the flowers on a tree in full bloom. Whether these poor flowers will be produced in water, we doubt. At any rate they are so unlike what are popularly known as *flowers*, that those who have been watching for them will be greatly disappointed, should they be produced. We noticed this "Alligator Plant" swindle when it began with a single vender, several years ago. That these branches should be sold to city people, is not strange, but when we see several persons on a ferry boat going to New Jersey, where the twigs came from, and to Long Island, where, if we mistake not, it is not rare, we wonder what these grown men have been doing with their eyes all these years, not to know the branches of the "Bilsted," the name often given to it in New Jersey and around New York. Becoming disgusted with the extent of the swindle, which, though small upon each person, was very large in the aggregate, we wrote a full explanation to Mayor Ely, who courteously replied that he had put it in the hands of the Chief of Police, and as we have since seen no more of the plants offered, we suppose it was stopped by the proper authorities. Those who may be disposed to try the sale next spring are hereby notified that we shall be on hand to "nip it in the bud." The Mayor of Philadelphia will do well to note this item, for though the *American Agriculturist* circulates very largely in and about that city, there are there, as here, still some hundreds of thousands of people who have not got the guardianship of this Journal against humbugs, large and small.

That Butter Compound.

We knew it several years ago. It was in Ohio, and was called the "Golden Butter Compound," and was put forth, being in the "Buckeye State," by a "Bnekeye Co." in a small town in Ohio. After much circumspection, we obtained a sample, but not in such a manner that we could trace it direct to any particular person or "Co." Just then it turned up in Hartford, Conn., and we thought we were sure of it. The friend who kindly undertook to "interview" the "Butter Compound" chap was very faithful to his task; he went to the place and found an office "with a hole in the door" for letters, but our friend could never find the "Butter Compound" chap in. After a while, the "Butter Compound" turned up in Massachusetts. Then we said to ourselves, "the chap has reached his jumping-off place. He is where they don't stand any such nonsense. He is in the land of 'Milk-Cows and Dairy-Farming,' where butter, at less than \$1 a pound, has no sort of chance, beside the gilt-edged," and we were sure that that one offering to produce the "best of butter," and that at "a cost per pound never exceeding four cents," would either be suddenly squelched, or companies would be formed on State St., only less rapidly than they were in the days of the Lake Superior mining times, and this butter-business he put upon a regular square-toed basis. But we heard of no movement in Boston to make butter "at a cost per pound which never exceeds but four cents," and supply the world, nor did we hear of any movement to show up the matter. Knowing that the gentlemen of the "Mass. State Board of Agriculture,"

and those of the "Mass. Society for the Promotion of Agriculture" were very much in earnest in all that relates to the agriculture of their State, we made an appeal to these bodies, through the *American Agriculturist*, in all earnestness, to look into the matter, as we knew, better than they, what mischief was being wrought by this offer of the "Butter Compound" from South Framingham, "right under their noses," so to speak. Before these bodies were heard from, an Agricultural Editor from Boston made us a call, and we asked him why this "Butter Compound" business was allowed in Massachusetts and—in all places in the world—in the vicinity of Boston. This gentleman informed us that all their knowledge of the matter was obtained from the *American Agriculturist*, and that these South Framingham circulars did not "circulate" around home. He had never seen one, though living within a few miles of the place whence they are issued, while we had them by scores. We certainly can not blame the associations above referred to for not before acting in the matter, when a gentleman prominent on the agricultural press of Boston had never seen one of these "Butter Compound" circulars, until we gave him one! Recently we have heard that the Trustees of the "Mass. Society for the Promotion of Agriculture" have taken action in the matter. They have procured samples of the "Butter Compound," and have had analyses made by some of the chemists of Boston and vicinity. The analyses show the "Compound" to consist mainly of "Common Salt," "Burnt Alum," and "Sulphate of Soda," and perhaps small quantities of other salts, of little consequence. The important constituent is the alum, well known for its ability to curdle milk, but through the ignorance of the "Compound"-makers, the alum, in the samples tested, was *over-burnt* and thus made nearly insoluble. Some of the gentlemen interested in the matter, made a trial of the Butter Compound, "according to the directions." We do not know what their directions were, but infer that they were essentially those sent out by the Ohio "Buckeye Company," which are as follows:

DIRECTIONS FOR USING COMPOUND.

Take a pint of fresh unskimmed milk, and as much of the Compound as you can heap on a nickel cent, and thoroughly mix the milk and Compound together, in the churn; add to this one pound of soft butter, and churn until the whole mass has come to butter. If everything is of right temperature the butter should come in from one to two minutes, sometimes it takes a little longer. If you desire to give the butter a color take a small quantity of annatto and dissolve in hot melted butter; a teaspoonful of this will be sufficient to color two pounds of butter. The juice of carrot may be used, and is an excellent coloring matter. The yolk of an egg is good, but butter colored with it will not keep sweet so long.—Be sure to add salt before churning. Make the butter into roll without working. These proportions will make two pounds of butter, the extra pound costing about five cents. By increasing the proportions any quantity can be made at a time. The cream butter used should always be made pliable so the dasher will go through it easily; the milk should be lukewarm, same as if just from the cow. Churn should always be scalded and warm enough to prevent chilling the milk. To make a small quantity a small churn should be used. After churning put the butter away and let it get hard, and it will keep as long, and be as good, as pure cream butter. If you do not understand making butter, get some one who knows how, to test it for you, and you will find the Compound to work like a charm. The butter being just as good without being colored, it is not essential to use coloring matter except to make it look better.

The gentlemen who made the trial—and who are well known as practical dairymen—followed the instructions carefully. They took the requisite quantity, 1 pound of butter, the pint of milk, the required quantity, "enough to lie on a nickel cent," of the Compound, and churned according to directions. When they had gone through with it all and worked the butter in the usual way, they had as a result just *one pound of Butter!*

As already stated, the analyses showed that the alum had been so overburned, as to be insoluble. Had the alum been properly "burned"—the water of crystallization merely driven off—the alum would have been soluble and would have coagulated the milk and made what almost every housekeeper knows as an "alum curd."

Now what does all this "Butter Compound" amount to? Simply this, when made as it is intended to be, it is burnt alum and salt. What does it produce, when used according to directions?—Butter—genuine butter—"cream butter," the directions say—as if there could be any other! Is swished about in a churn with milk, to which this burnt alum stuff is added. The alum will, of course, curdle whatever is coagulable in the milk, and this curd, or incipient cheese, is mixed up with the real butter, to increase its weight. At the end you have butter with some very poor cheese mixed through it, or some very poor cheese made very greasy with real butter.—"You pay your money, and takes your choice." The whole thing is one of the very worst forms of fraud, and the gentlemen of the "Board of Trustees of the Mass. Society for the Promotion of Agriculture" are entitled to the thanks of the agricultural community of the whole country for what they have done in exposing this very mean fraud upon farmers. Now let them prosecute the South Framingham concern for obtaining money under false pretenses—for, sure, their fraud don't work—the alum, Jones, is *burnt too much*—and shunt that thing up.

P. S.—Since the above was in type, we learn from good authority, that a complaint has been made to the Post-

Office Department as to Jones & Co., whose business is by no means confined to the "Butter Compound."

Hay-making Machinery.

There is no more profitable expenditure of capital in agriculture than that for labor-saving machinery, and there is no more useful machine for the relief of human labor than the mower. As a matter of calculation it is easy to show that, where only 10 acres of grass is to be cut, it will pay to have a mowing-machine, hay-rake, and horse-fork. With regard to mowers, we have from time to time given the results of our experience with different machines. While old favorites are still excellent and have their good points, new improvements are constantly coming out. We now record the experience

Fig. 1.—FORK OPEN.

of a careful test of the Champion mower, formerly mentioned as the Haymaker or the Champion Hay-maker. This machine, being unlike any other, and possessing a novel motive apparatus, deserved a thorough trial. A machine was put through every possible test last season, both personally by the writer, and by several neighboring farmers, during a lengthened season of hay-making, with the result that it was found excellent in all circumstances. The draft is light, the ease with which it works, and the noiselessness of its motion are perfect; the knife will run at any angle, and the bar may be lifted perpendicularly, while the machine is operating, so as to pass a tree closely without putting it out of gear. It will start in the grass with ease; it will cut low or high, or take up lodged grass; the knife may be raised at either end or altogether, from an inch to a foot, so as to pass over stones or obstructions, while still cutting. There are no gears; no pitman; the only two cogwheels used are enclosed and safe from dirt; there is therefore no rattle, and the risk of breakage is reduced to a

Fig. 2.—THE GARDNER HAY-FORK.—Fig. 3.

minimum. The absence of machinery is so striking, that one fancies the mower consists of a pair of wheels, an axle, and a cutting-bar, and a seat for the driver, there being nothing else conspicuous about it; yet the strength and solidity of all the parts are apparent. On the whole it is the most valuable improvements in modern harvesting-machinery.

Another improvement that has come to our notice is the Gardner hay-fork, shown in the illustrations. The advantages of this fork are readily perceived. It can take the largest hold of any fork we know. (See fig. 1.) It can be used with hay, straw, grain, corn-fodder, manure, or short straw, such as buckwheat or clover-seed straw. When closed, as seen at figure 2, the load is safely gripped, and the arrangement of the draft-rope and carrier is such that it cannot be tripped without design. Fig. 3 shows the position of the fork when tripped. The fork, when it ascends, is caught and held in the car, and relieves the draft-rope from all strain or weight. This apparatus is the invention of an ingenious farmer of Orange County, New York.

Experiments with Potatoes, Beans, and Rutabagas, on Farm of Maine State College, at Orono, by Mr. G. W. Lufkin.

Soil: Sandy loam, quite stony, well drained. *Previous Treatment:* In pasture previous to 1875, then summer-tilled; in 1876, had stable-manure, four cords per acre; crop, mixture of wheat, oats, and barley; yield, 20 bushels per acre. *Size of Plots:* The whole experimental area was $2\frac{1}{2}$ rods long, and a little under 4 rods wide. This was divided lengthwise into strips 3 feet wide, each of which served for one row of plants. Alternate strips were manured, and served for the experiments, the intervening ones being left unmanured. The area was cross-divided into 3 equal divisions, each $\frac{1}{3}$ rods long. Division I. had Potatoes, II. Beans, and III. Rutabagas. Each experimental plot was therefore $7\frac{1}{2}$ rds. \times 3 ft., one one-hundred-and-twentieth of an acre. *Amounts of Fertilizers:* 800 lbs. per acre. *Application of Fertilizers:* A single shallow drill was made lengthwise through each strip, the fertilizers strewn therein and mixed with the soil. *Seed put in:* June 9. Potatoes, cut with two eyes on a piece and dropped one in a place at intervals of a foot; Beans, the "Yellow-eyed," 4 in a hill, hills 1 foot apart; Turnips sown with hand seed-drill. *Weather:* June and July dry, August wet. *Harvested:* Potatoes, Sept. 8; Beans, Sept. 14, poor crop; Rutabagas, Oct. 5, very good crop. *Costs and Valuations:* The cost of fertilizers includes price in New York or Boston, plus \$5.00 per ton for freight and \$2.00 per ton for applying. The potatoes are estimated at 75 cts. per bushel of 60 lbs.; beans at \$2.75 per bushel of 67 lbs.; rutabagas at 25 cts. per [measured] bushel.

* That is the most valuable fertilizing ingredients. + Increase (or loss) as compared with unmanured plots. 1. Plaster consists mainly of sulphuric acid and lime. 2. Kainit contains about 12½ per cent "actual potash;" the bulk is made up of common salt and magnesium compounds. 3. These contained probably 9 to 12 per cent of available phosphoric acid and 2 to 3 per cent of nitrogen. 4. Raftery and Williams'. 5. Plants grew well until the middle of July, when they died.

Science Applied to Farming.—XLI.

More about Farm Experiments with Fertilizers.

How the "Maine State College of Agriculture and Mechanic Arts," is teaching its students in agriculture in the field as well as the class-room, and helping them to teach it to the farmers of their State also, is shown by a series of experiments, made last season by a student, Mr. Lufkin, under the direction of Prof. J. R. Farrington, of whose good doings I have had occasion to speak before.

The report fairly bristles with points of practical importance. Let me ask the reader to study the descriptions and figures carefully, referring to the article in the April *American Agriculturist*, for explanations about fertilizers and technical terms, and to note: (1), In these experiments, potash salts, alone, did little apparent good, and fell far short of paying their cost. Among the crops most apt to be helped by potash, are grass, potatoes, roots, and the leguminous crops, which include beans. None of these got any considerable good from the potash here. Mr. Farrington has had similar experience with kainit, before, and found leached ashes as good as unleached. (2), Phosphoric acid helped the crops in every case. The best yield of each crop, potatoes, turnips, and beans, was with phosphoric acid, alone or with nitrogen. (3), The only case where dried blood alone seemed of any use, was with potatoes; but with superphosphates it evidently increased the crop in several cases. (4), Taking all in all, as tested by the crops and fertilizers named, the chief need of this soil seems to be phosphoric acid, and next nitrogen. In its present condition it does not call for potash.

Artificial Fertilizers bring Profit on some Soils and Crops, but Loss on others.

(5), As indicated by the experiments, this is one of the soils on which artificial fertilizers of the right kinds, and with the right crops, can be used with great profit. It is what the Germans term a "thankful" soil. Weak of itself, with a very little help it brings good crops. On the supposition that the single plots without manure were fair samples of the whole, according to Mr. Lufkin's figures, the nitrogenous superphosphates gave, with potatoes and turnips, a gain of from \$50 to \$80 per acre. With beans, on the contrary, there was almost uniformly a loss. Mr. Lawes, of England,

says, as the result of 30 years' experimenting and practice with fertilizers, "it is not advisable to sow artificial manure with beans, peas, tares, or other leguminous plants. Corn, [i. e., grain and root crops,] will take all the artificial manure which the farmer can afford to pay for." (6), The indirect action of the fertilizers evidently counts for a good deal here. The yield seemed to be increased by almost anything, and in a way that can hardly be accounted for by the direct supply of plant-food.

This is certainly a very creditable experimenter. Still it has some defects. These, however, I do not regret. As a wise old Roman writer on agriculture, Columella, says, "There is no occupation in which we cannot learn from our errors." (7), One defect is the lack of unmanured plots for comparison. If there had been three, one in the middle and one on each side, as recommended, we could have told much better whether the soil was uniform, and what it could do of itself. Still the inferences above, seem to me, on the whole, warranted. (8), In such experiments, generally, the gain or loss on a single plot is not an accurate measure of what it would be on a large scale.

(9), The plots were very small, four square rods, instead of ten, as suggested, but had the advantage of being long and narrow. At the same time so many concurrent results do show, I think, that, in its present condition, this soil needs phosphates more than anything else to enable it to bring good crops. (10), If Mr. Lufkin had not taken much pains to mix the fertilizers thoroughly with the soil, the heavy dressings on such small plots, 800 lbs. to the acre, would have been apt to injure the crops badly. As it is, I suspect that the trouble with the rutabagas on plots 1 and 3, was that the dried blood and the potash salts were too strong for the plants.

Practical Applications—What Fertilizers to Use.

In Mr. Birdsey's experiment described in the February article, potash salts brought the best results. His general experience tells him that guano, phosphates, and bone, which furnish nitrogen and phosphoric acid, do not pay. I think he is clearly justified in putting potash on that soil, and will be, so long as it brings him good crops. Mr. Bartholemew, on the other hand, found phosphoric acid uniformly beneficial, and got very little benefit from anything else. He ought to confine himself more closely to phosphates. Mr. Farrington had the

best results with phosphoric acid aided by some nitrogen. So long as his field is in its present condition, I think he need not apply potash. His soil may be like that of Mr. Lawes' farm in England, which has proved capable of keeping up a full supply of potash through more than thirty years' cropping, and has, during that time, given as good crops with nitrogen and phosphoric acid, in chemical fertilizers, as with annual and heavy dressings of stable-manure. Meanwhile I think both Mr. Farrington and Mr. Bartholemew ought to make comparative trials—with superphosphates, bone, fish, and guano of various grades—in order to learn which will be the most economical sources of the needed ingredients, and how profitable each will be. In cases like Mr. Sage's, where the complete fertilizer, only, was successful, if the results are confirmed by future experience, the complete fertilizer will be in place. All ought, however, to make the most of what their farms produce, and piece out with whatever else they find to be the best and cheapest.

What may happen in the Future, and with other crops.

If Mr. Farrington keeps on applying phosphoric acid with a little nitrogen, or Mr. Bartholemew phosphoric acid, or Mr. Birdsey potash alone, while the crops are taking these away, and other ingredients with them, the time will be pretty sure to come when these will be accumulated in excess, and the others relatively deficient in the soil. Nor would it be wise for Mr. Birdsey to depend on potash salts, or Mr. Bartholemew on phosphates alone, for all kinds of crops. If either one is to grow wheat next season, some nitrogenous manure, say nitrate of soda for Mr. Birdsey, or Peruvian guano for Mr. Farrington, would very likely be profitable. If Mr. Bartholemew or Mr. Farrington were going to seed down to grass, I should advise bone, which, with a good deal of phosphoric acid, would supply also a little nitrogen, rather than a "plain superphosphate" without nitrogen. And if they want to put in clover and keep it in, a dressing of ashes with the bone would help it a good deal, and for that matter would improve the grass also. So Mr. Birdsey would be apt to find that a little superphosphate would improve a turnip crop even where his corn had seemed to ignore it. And in either case phosphates, Peruvian guano, dry ground fish, and the like, might be very useful to force early vegetables for the market.

W. O. ATWATER,
Wesleyan University, Middletown, Conn.

Contiguous Houses, Costing \$1,000 each.

BY E. B. REED, ARCHITECT, CORONA, LONG ISLAND, N. Y.

These plans were originally prepared for six connected cottages, just completed, for Mr. Fred. Storms, (manufacturer), at Bayside, L. I. They

Fig. 1.—FRONT ELEVATION OF ROW OF SIX HOUSES.

were designed to give the largest amount of accommodation, convenience, and finish, possible, for one thousand dollars each, and are especially adapted to rapidly filling localities, or manufacturing districts. By this system of building in blocks, a very large saving is made in materials and labor, at first, and little expense is required to keep them in order afterwards. Where desired, the introduction of gas, or water-pipes, may be made, from one to the other direct, at small cost. Such connected houses are really more comfortable than separate ones, as they protect each other at their sides from the extreme changes of the outward temperature; and are therefore warmer in winter, and cooler in summer. The site chosen in this case is elevated, and has a westward frontage, securing the important advantages of good drainage, and the admission of direct sun-light to every room.

....**Exterior**, (fig. 1).—Building in blocks is a favorite mode with many large owners of village property. The chief objection to a majority of such erections is their formal and stiff appearance, arising from a monotonous uniformity, a repetition of parts, and the overpowering predominance of horizontal lines—partaking too much of the city-street style. To overcome such objections in this design, simple but effective irregularities were introduced, so that really no two dwellings are alike. The sky-lines are broken and varied; the main roofs have pedimented projections—with Mansard sections intervening; all horizontal lines are either shortened or omitted, leaving vertical ones to prevail, and the window openings are varied in their form and distribution. While these several features are essential to the good appearance of such buildings, giving them the pleasing elements of variety and picturesqueness, they do not add very materially to the cost. Cottages designed for simple dwellings, whether built apart or connected, should, as far as possible, preserve their identity as cottages, and if destined for undulating and picturesque situations, should be outlined to accord with their surroundings.**Interior**.—The following description of rooms has reference to the house at the extreme left; its relation with the adjoining one is shown by the dotted sketch at the side. All have equal accommodations; this and two others are similarly arranged, the remaining three have their sides reversed.**Cellar**, (fig. 2).—Height of ceilings 6½ feet. It is thoroughly floored, has outside entrances front and rear, and being well out of ground, is light and airy, and is adapted to general

use for the coarser work. Bins for coal are placed where they may be readily filled from the front window. One corner is partitioned off for a bath-room and water-closet. The window to the latter is shielded by a latticed inclosure beneath the rear lobby, adding to its privacy. The rear area not being protected by the rear stoop, has hatchway

doors to be used in stormy weather. The Stairs lead from near the front door, to the main hall of the first story.**First Story**, (fig. 3).—Height of ceilings 10 feet. A Hall, Parlor, and Living-room are embraced in the divisions. The hall is entered from a neat porch, contains the main stairs, and leads to the parlor, living-room, and the cellar stairs. The parlor is pleasantly arranged with double windows in front, has neat stucco cornices and centers, and a marble mantle. The chimney-breast is placed to allow sufficient space between it and the central partition, for a piano, or other large piece of furniture. The living-room is of good dimensions and shape, has two windows, a closet, a large fire-place, and a sink. The door leading to the rear lobby has glass upper panels, admitting additional light in the room in pleasant weather,

balance of the loose earth being used to fill more depressed grounds). All interior cross-walls of brick are omitted, their places being supplied with brick "footings" and framework. These brick footings are laid in trenches 4 inches below the cellar bottom, and are 8 inches high and wide. Sills of 4x6 timber are laid on the center of these footings (edgewise), leaving a margin of 2 inches on each side for the support of the ends of the cellar-floor beams. Girts are put above the sills (also of 4x6 timber), anchored to, and level with the outer foundation walls, and are supported by studding and braces, thus forming an inexpensive and substantial division and bearing between the cellars. The principal frame is of regular sized sawed timber, thoroughly framed and braced. The sidings are of clear pine clapboards, laid on hard-rolled sheathing-felt. The upper roofs are covered with IC charcoal tin, "tern-plate," and the Mansard sections are slated on hemlock hoards. The interior flooring is of 7-inch milled spruce; outside flooring of 4½-inch milled pine. To prevent the transmission of sound, all the main divisions of framework between the houses are deafened by a filling of pale brick and mortar. The cellar ceilings and side walls are white finished on one coat of brown mortar. All other plastering is hard-finished on two coats of brown mortar. Circular ventilators are placed in each gable, and two ventilators made to resemble the chimney tops are placed on the higher or central ridge of the roof, to allow for the escape of heated air from beneath the roofing. All windows have 1½-inch sash, of four lights each; those in the cellar are hung with butts; all above are balanced with iron weights, and have outside blinds. The doors are first quality, four-panelled. The interior casings are of clear pine, and are neatly moulded, and the parlor windows have panelled hacks. The Painting is done as described

Fig. 2.—PLAN OF CELLAR.

Fig. 3.—PLAN OF FIRST FLOOR.

Fig. 4.—PLAN OF SECOND FLOOR.

when the lobby door will be likely to stand open, and through it the lobby will be lighted at night from within. The main stairs, leading to the second story, are of the "quarter-circle" pattern, and are neatly finished with hard-wood railing, with a niche above.**Second Story**, (fig. 4).—Height of ceiling 9 feet. This story is divided into a small Hall, two Chambers; two Bedrooms, and three Closets. Each of the rooms is well lighted, and chimney-breasts, with marble shelves, and stucco trusses are finished in each chamber.**Construction**.—The average depth of the excavations below the surface is three feet. The Foundation walls are of brick work, 8 inches thick, those for the exterior are 7 ft. 4 in. high, showing an average of 4 ft. above the final grades. (In this particular case, the site being elevated, only 4 inches of additional filling was required in the grades, the

in the *American Agriculturist* for June, 1877, except that the blinds are of a chocolate color.

Estimated cost of materials and labor:

Mason's materials and labor	\$1,350.00
Lumber of all kinds	1,150.00
Tinning and Slatting, (complete)	300.00
Rolling Lining, \$30; Porches and Lobbies, \$275	305.00
Cornice materials, (prepared at mill)	120.00
Sash, Doors, and Blinds	400.00
Stairs, with outside Steps, with Railings	500.00
Shelving and Sandries	325.00
Nails, \$55; Hardware, \$300	355.00
Painting, \$300; Cartage, \$85	385.00
Carpenter's labor, (not included above)	800.00

Total cost of Six Dwellings.....\$6,000.00

Mr. Storms added about \$1,000 to the total cost of six buildings in plumbing, sewers, gas-pipes, and in fencing separate front and rear yards, to each house. As these improvements are not generally required, they are omitted in the estimate.

White-Crested White Polish Fowls.

The Polish fowls are known by their very conspicuous crest. The origin of these crested fowls is somewhat obscure. Cuvier and Buffon mention them, but are unable to fix upon their original source. It is supposed that they were first described by an Italian author, about 260 years ago, in whose treatise rough wood-cuts of some crested fowls were given as "Paduan Fowls." Padua was an Italian city, and these crested fowls were, therefore, Italian. Buffon refers to the Paduan fowls, and supposed them to have been descended from Asiatic stock; he also described a variety with white body and black crest, which has long been extinct, although breeders have made many efforts to restore it. The varieties of the Polish fowls now known, are the White-crested White, the White-crested Black, the Golden, and the Silver-spangled, with some bearded varieties. Of these, the

most beautiful is, perhaps, the first mentioned, the portraits of a pair of which are given on this page. This pair was bred by H. T. Sperry, Esq., of Hartford, Conn., who has devoted ten years of his leisure from journalistic duties to their careful culture. He has made a specialty of this breed, and has imported fowls, at a cost of \$130 in gold the trio, for the improvement of his stock. The Polish fowls are profuse layers, non-sitters, delicate table fowls, of handsome appearance; they possess an oddity in their crests, which makes them attractive to the fancier and the amateur. They are contented in confinement, and bear close quarters very well; are easily kept within bounds, and becoming readily attached to their owners, make pleasing pets. When young, they are unusually elegant with their full crests, gracefully shaped little bodies, and tame disposition. On the whole, there is hardly any other breed which would give more satisfactory results in every way, where but one is kept, than this. It is somewhat strange, therefore, to find that Mr. Sperry is the only amateur who has devoted time, attention, and money, to the breeding and improvement of this variety of fowl as a single specialty. As a matter of course, it is easier to excel in one thing than

in many, and Mr. Sperry's success at the exhibitions over other breeders, is the natural result of his singleness of purpose and perseverance. For some years back, he has taken the principal prizes at the poultry exhibitions wherever his birds have been shown. For ornament, the pure white breeds have a decided advantage over the colored ones, because they show so conspicuously upon a green lawn or a field. The White Leghorn is very popular on this

account, as well as for its prolific egg-producing; but the White Polish has an advantage over the graceful Leghorn in the possession of a crest, a heavier body, and better flesh, as well as being equally valuable as an egg-producer. For ornament, therefore, as well as for use, the White Polish should be

A SOUTH AMERICAN PENGUIN.

popular fowls. Perhaps they have formerly suffered in reputation somewhat from vicious breeding in the hands of persons less conscientious than Mr. Sperry. The breeders we refer to are fortunately not Americans, for it is to our breeders that these fowls owe their restoration to their old vigor and constitution. As in other particulars, so in this less important one, our poultry fanciers have been able to beat foreign breeders at unfavorable odds.

The Penguins.

Under the common name Penguin, are included birds of the Southern Hemisphere, which are placed

the South Pacific in such numbers that the accounts of explorers in those regions as to the extent of the flocks, and the manner in which they cover the shore, seem almost incredible. It was formerly supposed that the immense guano deposits of the western coast of South America, and neighboring

islands, resulted from the accumulated dung of these birds, though some recent naturalists do not accept this view of the origin of the guano deposits. The acquisition of a fine specimen by the Royal Zoological Gardens (London), allowed "The Field" to present the portrait which we have re-engraved. The plumage of this bird, when old, is of a dark-brown color, the breast being white, spotted with brown. But soon after moulting it undergoes a change. In the moult, the feathers do not fall off singly as is usual with other birds, but in flakes and large scales. The new plumage, when complete, is dark-bluish-black on the back and wings; a white line passes over the eye towards the crown of the head; the breast and

belly, and under parts of the wing, are white; a broad black line borders the white all around from the throat to the tail. The Penguins are all most expert fishers and divers, and dart through the water with the greatest activity. Upon land they jump and wabble about in a most ungainly fashion, their movements being somewhat as if their feet were tied together, and present a ludicrous mixture of hopping, shuffling, and falling about. Of the habits of the Penguins, we have a graphic description by one of the company of the exploring ship "The Challenger," in his "Log Letters." The writer describes what is known as one of their "rookeries," or nesting places, as follows:

"Between the foot of the cliff and the beach was a bank covered with long tussock grass, among which the Penguins had their nests, and from which they had regular roads into the rookeries. Among the stems of the tall tussock grass they were sitting about in thousands on their nests, consisting of a layer of grass. It was not pleasant walking in the rookery; horrible smells, to say nothing of the fierce digs we got in our legs, and the fiendish noise—something between the last notes of a donkey's bray and a deep-voiced sheep—a perfect roar which is kept up night and day, and plainly audible from the ship, sounding on a still night like the roar of a heavy surf. They never had more than two eggs, sometimes only one, larger than a Dorking's, colored

WHITE-CRESTED WHITE POLISH FOWLS.

by naturalists in three or four different genera. They are all found upon the sea shore, and are similar in their habits to the related Auks of the Northern Hemisphere. The general appearance of the Penguins is shown by the engraving upon this page. These birds are found upon the islands of

dirty-white with brown stains. The young, just out of the egg were black, naked things. Many of the eggs were cracked by the young inside, who were poking their bills out. Afterwards we walked back to the rocks where we had landed, a distance of five or more hundred yards, through the densest

part of the rookery, and ever to be remembered by me as the most awful walk I ever had. The grass grew six feet high, matted and tangled, while thousands and thousands of Penguins swarmed between the tufted stems. Whenever we stopped to see where we put our feet, we were instantly attacked by a host of infuriated birds, and got horribly tweaked and digged at. You can have no conception how infuriated and hold they are when protecting their nests, rushing at our legs in crowds, and following us, pecking viciously. They were so thick that it was useless trying to avoid them, so one had just to tramp on as fast as possible, amid the deafening brayings, and overpowering stench. Suddenly we were stopped by finding ourselves on the brink of a low cliff. This stretch of rock was covered with Penguins, one stream coming from the grass and putting to sea, and the other stream landing and hopping into the rookery. Marvellous jumps they made in coming down the rocks, doing a jump of three feet and more quite easily, bolt upright the whole time. They jump into the sea from off a ledge of rock feet foremost, and land very cleverly; as the wave came washing up against the rock, they came with it under water, shooting out of the depths in shoals, clinging on to the rocks by their feet, and when the wave receded the face of the rock was plastered with them, and before the next wave came they had elampered up in some wonderful fashion, helping themselves with their bills, but not with their flappers."

Among the Farmers.—No. 28.

BY ONE OF THEM.

Tramp, Tramp, Tramp.

There is no echo attending the muffled footfall of the army, the straggling forerunners of which already appear along the highways and in our door-yards. Where the tramp hibernates is, perhaps, still an undiscovered fact in Natural History. There is chance enough in the city, and many a snug corner in boiler-rooms, under sidewalks, and in coal-holes. I am curious to know, not where or what have been the winter quarters of this army, but whether the people are any nearer the solution of the tramp problem than they were a twelvemonth ago. I have the profoundest pity, not to say sympathy, for the poor fellow who is out of work, and can get neither work to do nor food to eat; but not a particle for the 20,000 able-bodied wanderers of the male sex, who make our quiet roads both hideous and dangerous. A visitation or two of locusts, rouses half the country, and even the General Government, to put them down; but this visitation of "hummers" is ten times as disastrous, and a great deal nearer home. So far as I am aware, little effort has been made to have more stringent laws passed in regard to this nuisance, and our people are waiting in apathy to see if the times, or the silver bill, or resumption, or some other occurrence, will not prevent the same condition of things happening as last year. It is very pleasant "to entertain strangers," but tramps are a kind of strangers who are so often entertained unawares, and who so often manifest a most unpleasant familiarity with your house and surroundings, that they are, as a class, in no way entitled to be regarded as strangers, any more than minks and foxes are. Arrest as vagrants, detention at steady labor, with enforced cleanliness and tidiness, and with good plain food, for as long a time as the law allows, will do away with the tramp nuisance and danger in a very short time.

How Often to Feed Work Horses.

There is a conflict of authorities on this subject, but writers agree that all horses ought to be fed as often as once in about six hours, during the day—some say four hours. No doubt, a horse may eat his fill and digest it in about six hours, and be ready for another ration. They may be managed so as to be ravenous for food all the time, and yet eat more than enough—and one set of horses will be in good condition, will do about twice the work of another set on half the feed. I have been watching the working of an experiment—if so it

may be called—which furnishes a case in point: A long established firm in New York employ constantly, and have heretofore owned, about five one-horse truck teams. That is, five horses have done their work, a considerable part of the time one having but little to do, but necessary in case of any emergency. Some months ago the entire stock of horses, trucks, stable furniture, harness, etc., was sold to an employé, who has, since then, added no new horse to the stable, done the same work, done the carting for another house—in fact, got nearly double the work out of the horses—and yet they have been constantly improving in looks and in ability to do work. At first the feed was not essentially changed. The horses had better care, and the eye of a master, who was their owner, though not their driver. The truckmen, somehow, felt more interest in their work and in their horses, and this made a difference; but all things combined must have produced their legitimate result within two or three months. At all events, matters were getting on very well, when the owner decided to

Cut Off the Noon Feed.

The horses had been getting about four to six quarts of oats during the hour of rest—between 12 and 1 o'clock—while the men were eating their dinner. I am not sure that they always got their full hour of rest, but they did generally. The result has been, a decided improvement in the condition of the horses, in their ability to work, and the gain of fully half an hour, when it is necessary to take it; for now, when work presses, the men are quite ready to forego their rest and, taking a hurried bite, be off with their trucks as soon as they can be loaded. The horses leave the stable at 7 o'clock, and return at about 6.30, the year round. Thus, they go twelve hours without feeding, and at more or less hard work, at a slow gait all the time, except when the trucks are being loaded and unloaded. When it is practicable, of course, loads are taken both ways, and this saving of time is also a saving of horse-flesh; for no doubt a heavy, well-fed horse is quite as much taxed in trotting home with an empty truck, as in drawing back a laden one. I should add that the horses are not deprived of the oats by not getting them at noon, for their morning and evening rations are increased, but not proportionately, there being a saving of about two quarts to each horse on an average. Nevertheless, they are now doing better, and looking fifty per cent better, as well as doing more work at less cost of feed than under the old method.

Horses' Habits in Lying Down.

One thing more about horses. I don't know why a horse should not be as much rested and benefited by lying down as any other four-footed beast. A horse often sleeps standing up, and so does an ox. I know that it was claimed for a gray horse once, as a special merit, that he would not lie down unless his stall was well littered; consequently all expense of bedding might be saved, as no doubt it had been. Horses are peculiar about lying down. It seems as if they knew their helplessness when in this position, and were bound never to expose themselves to danger. Although many may be lying down, every horse in a stable is on his feet at the slightest noise. It is, besides, almost universally regarded, and usually truly, as a sign of ill health, if a horse is found lying in the day time. I have recently come to the conclusion, however, that if horses are perfectly easy in their minds, they will take as much comfort in lying down as cattle do, and I can point to one stable, not my own, where spirited well-fed horses may be seen lying down at almost any time of the day or night, and it comes from the perfect confidence they have in their groom.

Chances for Farming.

With an overstocked labor market, and wages very low; with thousands of acres of farming land, which have been lying fallow, or rather running wild, for fifteen years, more or less, in every direction within fifty miles of New York, returning to the hands of the original owners, or to mortgagees, and with the best fertilizer in the world, the dung of well-fed horses fairly "going a-begging" for some one to buy and use it, I see no reason why we can

not again become a farming community. We have been in the habit of raising crops which would not bear long transportation—hence were adapted to the home market, which we could watch and take advantage of. Gradually steam communication with southern ports has made it almost as easy to send peas, potatoes, and parsnips, from Virginia or the Carolinas, as from Monmouth Co., N. J. Nevertheless, we have a great advantage in our ability to get city stable-manure. For this, Long Island is still the great market, yet transportation by boat to the Connecticut ports along the Sound, and up the Connecticut River as far at least as Hartford, for the use of the tobacco-growers, has been in vogue for some years. This year the tobacco men have no heart, and are turning their land to the raising of crops which can be consumed on the farm, or sold in the vicinity, and are buying no manure. The market gardeners of Long Island are so short of money, on account of the immense cabbage crop which went to waste last fall, that they are buying but little, and if railroads running through farming districts were as awake to their interests as is the Long Island Railroad, we should have a fertilizer at hand, which would make the waste land and old farms wave with wheat, and smile with potatoes. The Long Island road favors the farmers not so much in the matter of cheapness of transportation, which is not cheap, indeed, considering that the manure which they carry enables them to move sundry other articles of produce, and many passengers to and from the city, as in their willingness to accommodate those who live along their lines. They will throw off a car-load of manure at any point where it is most convenient to the buyer, if he will only set up a modest board with his name or "mark" upon it. Other roads ought to do the same thing, and besides should erect such cranes or derricks as can most conveniently move the manure from the boats to the ears.

The Supplying of Milk,

in the immediate vicinity of a large city, is certainly one of the most profitable branches of farming. Were farmers properly seconded by the city authorities, they would have no difficulty whatever in affording, at current prices, or say at six and eight cents a quart, as much pure milk as the citizens of New York will pay for. The close proprietorship of "milk routes" is one difficulty. The citizens have little idea that *they* themselves, and their children, are bought and sold like the very cattle whose milk they drink and get sick upon. A swill-milk stable, and its milk route, are sold together, and the route is just as much tangible property as the cows. Any farmer, or the agent of a company of farmers, who would undertake to sell, or even exhibit, pure milk along one of these established routes, would be mobbed; his cans would be emptied, or pierced, and the milk let out; or the milk would be drugged and so eurdled, or in some way spoiled. These things have occurred so often that the effort has been given up. The children pine for milk, which may be had in abundance if the City Government would only see fair play. What we need is

Free Trade in Milk.

As it is, it hardly pays to raise milk and sell it at three cents a quart, where land is worth more than \$100 an acre; and as that is all, or more, than we can often get for it of the milkmen, it follows that the milk business has been given up by our farmers to a great extent, and that now milk is brought from a great distance, or produced in the stables which abound in the immediate suburbs. A new impulse would be given to farming and stock-raising if farmers could dispose of their pure milk in the city. They would willingly submit to any sanitary restrictions, and their milk to any tests which would demonstrate either the presence of water, or any impurity; and the present seems a very favorable time to make an effort for free trade in milk. In connection with this abundance of manure, and the possibility of our being able to sell milk to compete with the watered and sickly stuff which drives people against their will to use condensed milk, instead of the natural product, I am led to think favorably of the effort now being made, with some success, to introduce the production of

Beet Sugar.

"Why people of sense call it beet root sugar, I can't see. What is a beet but a root?—that is all there is to it. We do not think of the tops when we speak the word, and to imitate the English is following a very poor example in matters of language; for I think they are as incorrect as they are opinionated.) It takes capital, and I verily believe it will prove a good investment for capital, especially in the vicinity of New York, where so much sugar machinery is lying idle, or earning so little. What modifications of the modern sugar houses it would require to enable them to work over the crude product of the beet sugar works, I do not know, but it seems as if the capital now invested, and nearly useless, might thus find profitable employment. On Long Island, along the Connecticut coast, in New Jersey, especially in Monmouth, Essex, and Bergen Counties, we have admirable land for beet raising, and we certainly have the manure. It will be easy to get the labor to do the work well, and yet not neglect the raising of all that market truck, which will be profitable one season with another. Whatever profit there might be from the beets, would be more or less regular—not subject to the same fluctuations and disappointments that attends the raising of cabbage and celery, and the like.

Farmers who consider this subject of beet sugar, must bear in mind that the sugar takes nothing from the soil—is no tax upon the land, the residuum, or pulp, after the expression of the juice, being returned to the farm for feeding stock. In this way a much larger stock of cattle is maintained, much manure produced, and the farm steadily benefited by the crop. Deep tillage, clean tillage, and high tillage, are enforced conditions, and wherever they are practised it is done profitably. The owners of a few reclaimed swamps in Louisiana, and of a few acres of "sugar bush" in Vermont, should not be the only ones benefited by the duties on sugar, when a large proportion of the farmers through the best parts of the Middle and Western States might enjoy the "protection," and share the advantages of the higher price of sugar.

Talks on Farm Crops.—No. 15.

By the Author of "Walks and Talks on the Farm,"
"Harris on the Pig," etc.

"I have known a fair crop of oats," said the Deacon, "sown as late as May 15, but, as a rule, in this section, if not sown before May 1, we stand a small chance of getting anything but straw."

"There are few crops," said I, "more dependent on the season than oats. If that is favorable, oats will stand much poor farming, and if unfavorable, it will tax all our skill to produce a large crop."

"We have comparatively few experiments," said the Doctor, "with artificial manures for oats, but those that we have, indicate that the manures best for wheat and barley are also best for oats."

"There can be little doubt on that point," said I, "but we might differ as to what manures are best for wheat and barley. All will admit that, where the soil has sufficient phosphoric acid and potash, available nitrogen is the one ingredient most needed."

"And yet," said the Doctor, "in the experiments quoted by Prof. Atwater, in the May No. of the *American Agriculturist* for 1877, page 171, nitrogenous manures did not increase the yield of grain, while they produced a greatly increased growth of straw. Thus the plot without manure produced 50 bushels of oats and 2,372 lbs. of straw. On the adjoining plot, with 357 lbs. of sulphate of ammonia, the yield was about 50 bushels of grain, and 4,049 lbs. of straw. With what is called a 'complete fertilizer,'—containing nitrogen, phosphoric acid, potash, and lime—the yield was 51 bushels of grain, and 4,387 lbs. of straw. Another plot, dressed with 178 lbs of nitrate of potash, 223 lbs. sulphate of ammonia, and 312 lbs. of plaster, produced 58 bushels of grain, and 4,176 lbs. of straw. This was the best yield in the field. The only practical conclusion to be drawn from the experiment is this:—So far as the production of grain was concerned, the land

was rich enough for the season. An addition of more plant-food increased the growth of straw, but had little or no effect on the grain. The oats on the 'no manure' plot weighed 43.2 lbs. to the bushel, while with a 'complete fertilizer' they weighed only 39.6 lbs. per bushel. This is additional evidence that a better 'season,' and not richer land was needed to produce a larger crop of grain."

"Well," said the Deacon, "what of it?"

"Simply this," said I. "Farmers have not merely to look to making the land rich, but they must get the crop in early. And to do this, the land must be drained, and made clean and mellow. Artificial manures are thrown away when applied to wet land. And it should be well understood that a dressing of manure, rich in nitrogen, might give us a large increase of spring wheat, barley, or oats, if sown early in spring, but if sown late, it may give us more straw, but a poor yield of grain. Mr. Lawes ascertained this fact a quarter of a century ago."

"But suppose," said the Doctor, "you had a piece of rich land, or land heavily manured, that you wished to sow to oats, but could not get them in early, what would you do in such a case?"

"Plant the field to corn," said I, "or drill it in with corn for fodder, or plant potatoes."

"Exactly," said the Doctor, "but this is dodging the question. I assume that you must sow oats."

"Very well, then," said I, "sow them, and run your chances. If your land is rich enough, you might find the oats a capital crop to cut and cure for hay. Where timothy hay finds a ready market at good prices, farmers can feed their horses much cheaper on oat-straw than on hay."

"That is so," said the Doctor, "but if the horses are at hard work you will need to feed more grain or bran with the straw than with the hay. There is nothing I like better for my horses, especially for a change, than to take oats in the sheaf, and run them through a feed-cutter. A quart of corn-meal, three times a day, mixed with the chaffed oat-straw and oats, will keep a horse in good condition, and, as you know, I have to drive my horses over heavy roads, and in all kinds of weather. Six pounds of this chaffed oat-straw contains about 2 lbs. of oats."

"When oats are to be used for this purpose," said I, "the crop should not be suffered to get fully ripe. When cut green the straw is more succulent, and if properly cured, the horses will not only eat it with a greater relish, but the nutriment it contains is more easily digested. We have a splendid climate for curing the crop. If cut with a reaper, and thrown off into sheaves, and after lying exposed for a day or so to dry, it is bound and stuck up into shocks, the crop can be cured to perfection with little risk. The sheaves can then be stowed away in a small compass, and are much easier handled and cut into chaff than when the crop is put in the barn loose like hay. Still the method of curing must be determined by circumstances. If I had plenty of barn-room, or if I had to put the fodder in a stack, and if the crop was very green, and badly lodged, I should cut and cure it as I would hay, or as I cure oats and peas."

While the Doctor and I were talking, the Deacon had picked up the bound volume of the *American Agriculturist* for 1877, and was studying Prof. Atwater's article on page 171. "I tell you," said he, "if you were going to raise oats for hay, these artificial manures would give you a great crop. The superphosphate did no good, but about 50 lbs. of nitrogen alone, gave an increase of nearly 1,700 lbs. of oats and straw, and nitrogen and potash an increase of over a ton of oats and straw. The crop without manure was nearly 2 tons per acre, and the crop with the nitrogen 2 tons 16 cwt., and with the nitrogen and potash 3 tons per acre."

"Yes," said the Doctor, "and I would quite as soon have it as 3 tons of timothy hay."

"And the crop," said I, "only occupies the ground three or four months, and after harvest you can plow the land and sow it to wheat. On the whole, oat-hay is a crop worth trying on rich land."

"I suppose," said the Deacon, "that the oats would often be sown on black, rich, alluvial soils, not suitable for winter-wheat, and in this case it might be desirable to seed down with the oats."

"If the land was very fine and mellow," said I,

"we should risk but little in sowing grass-seed, even as late as the middle of May. Much depends on the condition of the soil. I once had a capital catch of clover sown on winter-wheat late in May."

I have for fifteen years let my married men, who live in houses on the farm, plant a few rows of potatoes in the field, with my own crop. We plow the land, and do all the horse-work, but they furnish their own seed, and do the planting, hoeing, digging, etc. Once or twice my crop has been better than theirs; but, as a rule, they beat me. Why? is a question I have often asked myself, but can get no satisfactory answer. The land and preparation are the same, and the cultivation is the same—unless, possibly, the cultivator is held more steadily, and is not allowed to skim over the hard spots. Their crops are no cleaner than mine. In fact, sometimes not so clean, but it may be that the hoeing and hilling are done with more care. The more a farmer looks at his cows and sheep, and horses, the better they thrive. Possibly my men, in hoeing their potatoes, look at each plant with more interest than they do at mine, and give the hill a few affectionate taps with the hoe.

Then, again, we usually, though not always, mark out shallow furrows with a plow, plant the potatoes in the furrow, and cover with the plow—and if any are not covered with the plow, we go over the field afterwards and pull soil on to them with a hoe. My men cover their potatoes with a hoe, and probably do not cover so deep.

"And what is equally important," said the Deacon, "if not more, they take pains to get some nice, mellow surface soil to cover with, while the plow in some places turns up and throws on the potatoes soil that is cold and cloddy."

"I am inclined to think," said I, "that I have been in the habit of planting my potatoes too deep. But a great deal depends on the soil and season. Two years ago, the author of 'Among the Farmers,' in the November No. of the *American Agriculturist*, page 414, writing during a great and protracted drouth, which had almost destroyed the potato crop in his section, came to the conclusion that we had been neglecting early planting. The best crop in his neighborhood was one planted early and well tilled. The plants were well established before the beetles or the drouth seriously affected them. But he thought early planting alone was not enough. Deep planting was nearly as important. 'If the soil be reasonably deep and mellow,' he said, 'the seed may be placed six inches deep, though I would not advise or direct that it be planted more than five, for this would accomplish the setting of the seed probably at something over four inches. This depth is usually about right, yet in sandy land six inches is none too much.' I have acted upon the same idea. But I have made up my mind to plant shallower."

Another thing I have made up my mind not to plant or sow so deep—that is mangel-wurzel seed. Last year we had very dry weather at the time I dibbled in the seed, and wishing to put the seed down into the moist earth, I covered them two or three inches deep. Some that were planted shallower came up far better. An inch is deep enough, especially if the land is rolled after planting, as it always should be, and the fine soil pressed firmly around the seed. Even in severe drouths there is more moisture in the soil than appearances indicate. The point is, to make the soil fine and mellow before sowing, and then to roll down firm and smooth. In such a case the moisture from below will rise near enough the surface to cause the seeds to germinate—and if the seeds sprout, there is little danger of their being injured by drouth.

WINTER OATS.—Although winter oats would be a very valuable crop in the Northern States, and it seems reasonable to expect that they will grow under favorable circumstances, our experiment with them the past winter has not been such as to induce any further trial. As they were widely advertised in northern agricultural journals last season, we decided to give them a trial, which was done at considerable expense for seed and freight.

The winter has been a very favorable one for them—indeed, it could scarcely have been better. The lowest temperature has been 4 degrees above zero, and there have been many warm growing days. Yet nine-tenths of the plants are now lifeless, and the rest, though they survive, are in a poor, weak condition. At present, we do not think that southern winter oats are a promising crop north of Virginia.

Preparing Corn-Stalks for Fuel.

Where corn is burned as fuel, some saving may be made by using the stalks in place of the grain.

Fig. 1.—FRAME FOR BUNCHING STALKS.

The excellence of the ears as fuel consists in their solidity, and consequent slow combustion; while the great objection to the stalks is their lightness, and the rapidity with which they are consumed. If the stalks be pressed into small compact bundles,

Fig. 2.—THE FRAME IN USE.

and bound with wire, they will burn much more conveniently. This may be done very easily. Make a frame of two pieces of plank, about six feet long, fastened together as shown at figure 1, and hollowed out to receive the stalks. The

bundle is kept in place by pins inserted in the holes shown in the planks. The planks may be about 18 inches apart, making the bundle about the same length. When the stalks, stripped of the leaves or not, are laid in the hollows, they are pressed tightly by means of a curved iron hook fixed in a handle, as shown at figure 3. The hook is inserted in a staple, shown at A, in figure 1, and the handle being pressed down brings the stalks tightly together, when they are bound with pieces of wire previously cut into proper lengths. The bundle is then moved on in the frame and bound again, and so on until the whole is made into a series of bundles, which are cut apart with an ax. At each place where the cut is made there should be two

Fig. 3.
HANDLE.

Fig. 4.—BUNDLE OF STALKS.

bands a few inches from each other, and the bundle is cut between these, (see fig. 4). The labor of preparing the stalks for fuel is less than that needed to cut and prepare fire-wood, and may be done under a shed during stormy weather. The bands, made of No. 12 or 13 annealed wire, may be raked from the ashes and used over again several times.

A Filter for Rain-Water.

A convenient filter for rain-water may be attached to the conductor from a roof at a point just above the surface of the ground, so that it can be reached easily, and where the pipe begins to curve towards the cistern. A box about two feet square may be made of cement, or of brick-work cemented

upon the inside. A shelf, or horizontal partition, of slate is built in the box, six inches above the bottom, and this is perforated with a number of small holes, to permit the water to pass through it freely. The slate may be easily perforated by means of a punch or sharp-pointed spike; if this is struck a quick blow with a hammer, a hole is readily broken through the slate. First place upon the slate, an inch or two of coarse, well washed gravel; upon this put a layer of clean, washed sand, and then, if thought necessary, some finely broken charcoal. Upon the top of these materials, some perforated slates are to be laid, to prevent washing by the falling water. The manner of making the filter is shown in the engraving.

FILTER.

Scare-Crows for Cornfields.

A ready method of protecting newly-planted corn-fields from crows, or blackbirds, is shown in figure 1. It is made of a light hickory, or other elastic stick, one end of which is stuck into the ground; to the other end is suspended a glass bottle, from which the bottom has been broken off. The cord by which the bottle is suspended passes through the neck; a nail is fastened to this cord to serve as a clapper, and so attached that it will strike the glass when the cord swings. A piece of bright tin, sheet-iron, painted shingle, or slate, is suspended to the end of the cord. When the wind blows, the suspended tin, or other article, is whirled in all directions, and causes the nail to rattle against the glass bottle.

Fig. 1.—SCARE-CROW OF BOTTLES.

Fig. 2.—BIRD SCARE-CROW.

at three sides, so as to roughly imitate a dilapidated bird. Carve a rough head from a crooked branch, and arrange the tail feathers in an expanded position to catch the wind, by which it is caused to dart hither and thither in a most unexpected manner. This arrangement is shown in figure 2.

Green Crops for Cows.

The use of green crops for soiling cows is becoming absolutely necessary. Every dairy and milk farmer with whom we converse, admits that without growing green crops for fodder, his profits grow smaller every year, or his cows fail entirely to pay their expenses. One cow upon pasture and hay alone, requires about seven acres of ordinary ground. 12 to 15 cows are about all that can be maintained upon a hundred acre farm with pasture, hay, corn, and oats. The cost of average farm land in dairy districts is say \$100 per acre. The interest on the cost of seven acres, at 5 per cent, is \$35 per year, and the average profits of such farm land should be at least 5 per cent. Few farmers

can see any such profit as this from their cows, after charging expenses and labor, although some may realize as much. But if, by the better management of their business, farmers can keep one cow upon two acres of land, and can make a profit of \$25 to \$35 per cow per year, then the land will return a yield of \$12 to \$17 per acre, or 5 per cent upon a valuation of \$240 to \$340 per acre. Land, like other property, is valued in proportion to what it produces. In England, farm land is worth, on an average, \$500 per acre, and as it is held to be the most secure of all investments, a low interest return is satisfactory. But at this valuation, the rent of land produces from 3 to 5 per cent per annum. It is valued thus highly because it is made to produce large crops. If our land should be made as productive as that, it would easily bear as high a value. Thus the profits from our land, as well as its value, depend altogether upon the amount of the produce grown. The value of green fodder crops consists not only in the heavy products raised, but in the possibility of growing two or three successive crops in one year. The land is always busy, and is constantly producing something that can be turned into money, or its equivalent.

Cementing a Cellar.

Damp cellars are by far too frequent for comfort or health, yet they are easily kept dry. The most effective method is to cut a drain 10 to 20 feet distant on the side from which the water comes, and two feet deeper than the cellar bottom. This will cut off the flow of water from the sub-soil, and lead it away. But some cellars are so situated that no convenient outlet for a drain can be found, and some other method must be provided. In this case cover the floor of the cellar, and the sides, if necessary, with cement. The materials used are Rosendale cement, gravel, and sand. The tools required are a mixing-board and shovel, a rammer (fig. 2), and a smoothing-plank (fig. 3). The cellar-floor is first to be leveled, all hollows being filled up.

Two barrels of coarse, sharp sand are thrown upon

Fig. 1.—BOARD FOR MIXING CEMENT.

the mixing-board and mixed thoroughly with half a barrel of the cement, the whole being spread in a heap, hollowed in the center, as shown at figure 1. Water is thrown into the cavity in the center, and the mixed sand and cement is shoveled towards the water and mixed with it, more water being added until a semi-liquid mass is produced. To this is added, gradually, twice the bulk of coarse-gravel, small stone, or broken fragments, previously wetted with water, and the whole is thoroughly mingled together. Every particle of stone should be brought into contact with the cement. The mixed concrete is then shoveled on to the floor, beginning at one corner, in a layer three inches thick; and as soon as the

Fig. 2.—RAMMER.

Fig. 3.—SMOOTHING PLANK.

material has been spread and leveled with the shovel, it should be well pounded with the rammer

until the surface becomes covered with semi-fluid cement. While one batch is being spread, another should be mixing. If the walls need cementing to keep out water that may penetrate through them, this should be done with the mixed cement and sand, without the gravel or stone. As soon as the

Fig. 4.—SECTION.

concrete is hard enough to walk upon, which will be in 24 hours, the finishing coat may be laid on. This consists of the cement and sand, mixed as already described. This is spread with the back of the shovel one inch thick, and is finished with a smoothing-board having a smoothly dressed and well oiled surface, made in the shape shown at figure 3. The piece of board should be about 3 feet long and a foot wide, and the handle so inclined as to be convenient to work with. When finished, the floor will appear in section as at fig. 4.

Improving Wet Meadows.

One of the most difficult of farm improvements is the reclaiming of swampy ground and overflowed meadows. At least it seems difficult, and

Fig. 1.—GURNEY'S FIELD LEVEL.

it is really the least satisfactory job a farmer can undertake, because its success depends upon more than usually skillful management rather than mere labor. To get rid of the water, drains are needed, and these must necessarily be made in such a way

Fig. 2.—POCKET LEVEL.

as to lead the water, either to the lowest portion of the land, or from it altogether, into the nearest water-course. These wet lands are generally so nearly level, that it is often impossible for any but a practised surveyor, with his instruments, to decide which way the water will run in the drains, and it sometimes needs the surveyor's positive assertion to convince owners of such lands either that the water can be carried off at all, or as to the direction in which the slope actually exists. After much experience with swamps and wet lands, it may be stated that, as a general rule, there are very few indeed that do not admit of some form of drainage by which they may be brought under profitable cultivation as meadows. The possibility of this may be decided at little cost by the employment of a competent engineer who has made a special business of drainage and irrigation, and who thoroughly understands the work, or by the use of some simple and easy mode of leveling by the owner himself. Several methods of finding the level are described in "Stewart's Irrigation for the Farm, etc.," from which we reproduce the foregoing illustrations of leveling instruments. At figure 1 is shown a field-level, made by S. & W. E. Gurney, which is a very

accurate instrument. With this are needed a "Jacob staff" to set the level upon, and a sighting-rod, marked with spaces of feet and tenths of a foot

Fig. 4.—DIRECTION OF DRAINS.

(or inches) above and below a standard mark, which represents the height of the instrument above the ground when properly set and adjusted. At figure 2 is a pocket-level, which can be used where it is impossible to plant a staff, and if used with skill, this is about as effective as a more expensive instrument. With this a sighting-rod marked is used at the exact height of the eye of the operator from the ground, and with feet and inches above and below this, as shown at figure 3. This instrument contains a spirit-level, the bubble of which is reflected from a sloping mirror within it, and is made to appear as if on the object-glass at the end, where it is crossed by a fine wire. When the wire cuts the bubble in the centre, the sight is on a perfect level, and the point on the rod can be marked by the person who holds it. When a piece of wet land is to be surveyed for draining, it is necessary for the surveyor to stand with his level at the supposed outlet or lowest point of the ground, and to

take a sight across the space to the other side, or in different directions. He will thus find with ease the amount of inclination of the ground, which will generally be greater than has been suspected. For instance, in one case where the owner of a piece of wet ground insisted that a certain point was the lowest part of it, this was found on examination to be 5 feet higher than the opposite point, and the drains, when made, flowed with a good current in the opposite direction from that expected by the owner. When the lowest point has been found, the outlet for the water should be made there, and if there is no way of escape for it beyond that, a pond may be made there to collect it. The drains should be dug from this point upwards, and by observing the flow of water any ordinary laborer will be able to carry them

Fig. 5.—FORM OF DRAINS.

along on a proper grade. This should be such as will permit a free flow of the water. At figure 4 is given a diagram of the manner in which the drains may be laid out from the outlet—in this case a brook—to the highest point of the swamp. The

Fig. 6.—TUSsocks IN MEADOWS.

courses shown are the drains from the sources of the water to the brook, and may be made in the most direct line. The drains in all these cases

should be open ones, as there would be an almost certain stoppage of tiles in soft mucky ground where there is no more fall than 5 or 6 inches in 100 feet. The form of the drain is shown in figure 5. To facilitate the use of the ground for a meadow, the ditches should be wide and shallow; 6 feet wide, and 1 foot deep at the center, and gradually sloping to it, is the form found most convenient.

As soon as made, these ditches should be sown with seed, and grassed over. When the surface of the ground is overgrown with tussocks of coarse grass, it will be the cheapest and easiest plan to cut these off by hand with a broad, heavy, sharp hoe, before plowing the ground. Generally they are in the shape shown at figure 6, and are easily cut off with a heavy hoe. These may be burned, when dry, and the ashes scattered over the ground. If the ground should become dry enough to plow, that would be the best method of leveling the surface. The furrows should be begun between the lines of ditches, so as to throw up back furrows, or ridges, in the highest parts of the ground, and leave the open furrows where the ditches will be made. In most cases, by good management, and a clear idea of what is to be done all through the job, nearly all the leveling may be done by the plow, harrow, and scraper, and only needs to be finished off by hand.

A Simple Foot-Bridge.

On a recent visit to a farm through which a small brook ran, there was much trouble in getting across the stream. To prevent such a difficulty is a very simple matter, but any provision for this, is one of the rarest things to find, even upon well appointed farms. A permanent bridge is not desirable in such cases, because of the cost of a structure that would resist the frequent freshets, and the ease with

A SIMPLE FOOT-BRIDGE.

which a light bridge is carried away. The better plan is to provide a plank, 2 inches thick, a foot or more wide, and of whatever length may be required, and attach it by one end by a chain or rope, as shown in the illustration, to a stake driven firmly into the bank. The other end is left loose. When a freshet occurs the plank is only displaced by the water, but not carried away, and can be readily restored to position when the water subsides.

How to Raise Ducks.

Most farmers have a prejudice against water-fowl, especially ducks. They tolerate geese better than ducks, because they will forage for themselves, and live wholly on grass through the summer, after the goslings are started. Ducks will not bear neglect so well; they are more prone to wander and get lost or devoured in swamps or brooks. They have a foolish way of dropping their eggs in water, and of following a brook, or river, into neighboring farms; unless they have suitable quarters, and receive regular attention, it is a good deal of trouble to look after them. The half-starved duck disposes of a good deal of corn at a single feed, remembering the past, and anticipating the future. The slipshod farmer is prejudiced against the bird, and will have none of him. But the duck has so many good qualities, matures so early, and furnishes so rare a repast, that the owner of a country home, with cultivated tastes, can hardly afford to do without a duck-yard. The flesh, in our esteem, is the greatest delicacy raised upon the farm, and if they were much more troublesome than we have ever found them, we should not hesitate to keep them. The fact is, a large part of the trouble is owing to sheer neglect, and the reputation of the bird as a gross feeder is owing to irregular supplies

of food. If grain, or other food, is kept within reach, they devour no more than other fowls that mature as rapidly. If in suitable quarters, and well fed, they get most of their growth in four months, and can be marketed in August at the watering places when prices are highest. The impression that a pond, or brook, is necessary to raise the ducklings, is erroneous. They need no more water than chickens until they are three months old, and are better off without any pond to swim in. We have raised fifty in a season in a quarter-acre yard, and found them no more troublesome than chickens. The best mothers are hens, and we prefer the Asiatic fowls, either Cochins or Brahmas. A hen of these breeds will cover nine or ten eggs. We have found an old barrel, with a board at the end, to fasten the bird upon her nest, as good as a more expensive coop. They are let off regularly at noon every day, when they have a half hour's range, green food, grain, and water. The young ducks are fed with some fresh animal food, and coarse Indian meal scalded, and this, varied with chopped cabbage, turnips, worms, and liver, is the staple food until they are three months old. They do much better on soft food than on grain.—The paradise of ducks is a location on a tide water stream or cove, where there is a constant succession of sea-food with every tide. If furnished with a little house, or pen, upon the shore, and a variety of grain, they will come home regularly every night, and lead an orderly life. The eggs are usually laid at night, or early in the morning, and very few of them need be lost. Of the four varieties, Rouen, Aylesbury, Cayuga, and Pekin, we give the preference to the last for size, early maturity, abundance of eggs, hardness, and domestic habits.

A Plan for Filling a Wash-out.

A correspondent in Georgia asks how to fill wash-outs, which are so frequent upon hillsides in the Southern States as well as elsewhere.
